radium needles supplemented by roentgen therapy. Both of these manipulative procedures contributed to earlier dissemination. While patients in group 3 receiving interstitial irradiation lived longer than those treated by roentgen rays, the facts are that the roentgen ray group included patients with distant metastases, while those treated by interstitial irradiation had inoperable cancer only because of local and supraclavicular extension.

In most articles presented on cancer of the breast, only the favorable cases are discussed. In other words, the operable patients receive the spotlight. I feel that the problem of cancer of the breast should be considered as a whole rather than from the favorable groups only. It must be realized that there are almost as many patients with inoperable as with operable cancers and that roughly 40 per cent of the operable group result in surgical failures. Education to bring the patient in early must go on, but as long as human nature is what it is, and procrastination continues, radiation plays a dominant part in the treatment of these patients. Further, there are facts that cannot be presented statistically, such as pain relief, growth control and the establishment of a degree of mental tranquility from knowing that something is being done. All this radiation offers and does.

While surgery is and will remain the best procedure to offer the operable groups, the survival period of those patients in whom the tumor has spread from the breast itself will be greatly enhanced by irradiation given either preoperatively or postoperatively. In my experience, preoperative irradiation is preferable to postoperative therapy, as it attacks the cancer cell in its natural surroundings. Excepting those patients who are to be treated exclusively by radiation, the aim of the treatment is not necessarily to sterilize the breast and lymph nodes but to inactivate the most actively growing cells so that the manipulation incident to the operation itself will not result in further dissemination. When our 39 per cent five year recoveries in the postoperative series, made up of both groups 1 and 2, are compared with the combined results of 52 per cent in the group in which preoperative irradiation has been used, the evidence points to the superiority of using irradiation before rather than after operation. The greatest drawbacks to preoperative therapy are due to two factors: first, the waiting period between the cessation of treatment until surgery is done and, second, the fear on the part of the surgeon of delayed healing after operation. Despite these objections, if the end results are improved the method is justifiable. The individual variation of surgical end results is apparently great. In the list compiled by Portmann,⁸ the five year results run from 15 to 52 per cent, while in a more recent report issued by the Presbyterian Hospital in New York, surgeons working with the same material have a five year curability of from 6 to 43 per cent. Obviously, some men are cancer surgeons while others are not. The same variability must exist among radiologists. While a competent technician and good equipment are necessary, it requires the careful supervision of a clinician who understands cancer and its mode of spread to get results. I realize that the figures that I have presented are not as high as those submitted by Pfahler,⁹ but this may be because of the fact that I have not recognized the importance of the saturation method of therapy.

CONCLUSIONS

When cancer of the breast is considered as a whole and not from the standpoint of the favorable groups, radiation plays a dominant role in its treatment. It contributes to longevity in all groups with the exception of group 1, in which radical removal alone is apparently sufficient. However, in group 2, preoperative irradiation as an adjunct to surgery increases the rate of survival between 15 and 20 per cent. While irradiation alone does not give the results that surgery does, interstitial irradiation approaches it, though permanence of recovery is not maintained after the five year period, as it is when preoperative irradiation and surgery are combined.

ABSTRACT OF DISCUSSION

DR. U. V. PORTMANN, Cleveland: Dr. Meland has grouped his series according to extent of involvement, which is the proper approach to statistical analysis of the results of different methods of treatment. He has placed patients with "no nodes" involved in group 1. In our experience at the Cleveland Clinic, and according to many reports in the literature, metastases in the axillary lymph nodes from cancer of the breast can be ascertained with certainty in approximately half of the patients subsequently proved to have them, after careful examination of tissues removed from the axilla. In our experience, and that of others, when no axillary metastases are demonstrable, from 80 to 90 per cent of patients survive five years by operation alone. But Dr. Meland finds that only 67 per cent of his group 1 patients having roentgen therapy followed by operations survived five years. Therefore it seems justifiable to conclude that some of his group 1 patients really had unrecognizable metastases; otherwise the survival rate should approximate the average of about 85 per cent. If one is willing to accept a higher surgical curability for patients without microscopic evidences of axillary extension, there is no indication from Dr. Meland's results that preoperative roentgen therapy added to the proportion of five year survivals. Dr. Meland found that exactly the same proportion, that is, 67 per cent, of patients treated by roentgen rays survived as those having preoperative roentgen therapy. It would appear that the radium destroyed the local tumor. However, it also is apparent that some of his group 1 patients had metastases; otherwise the destruction of the breast tumor would have resulted in a higher percentage of survivals. It is obvious from the statistics presented in regard to group 1 patients that the role of roentgen therapy was relatively unimportant. This also is suggested by his experience with roentgen therapy alone, since only 46 per cent survived. It is reasonable to conclude that, since the survival rates in his group 1 and group 2 A patients are the same, preoperative roentgen therapy did not add to the proportion of five year survivals. Fifty-four per cent of his patients in group 2 A and B having axillary metastases and preoperative roentgen therapy survived five years. According to our experience and reports in the literature, about the same proportion of patients having axillary metastases survive that long by operations alone. This also would appear to indicate that the preoperative irradiation did not increase the proportion of survivals.

DR. JOHN E. WIRTH, Baltimore: If I understood correctly, the author said he obtained a 17 to 20 per cent better result by preoperative irradiation. If that is so, I should like to know how he derived those figures and on what they were based.

DR. ORVILLE N. MELAND, Los Angeles: When it comes to the matter of discussing carcinoma of the breast, there is always going to be a difference of opinion. In the group 1 series there were some patients who started with roentgen therapy with the idea of avoiding surgery. As I mentioned, we left them in that group for the simple reason that we wanted to see what roentgen therapy could accomplish. Evidently it did not have any retarding effect, so a number of them who later went to surgery really were in group 2 when they had their operation. As far as the matter of treatment in these cases is concerned, the postoperative and preoperative, the conclusions that one draws from the

literature vary with different individuals. The matter of technic is one of the important factors. The patients mentioned from the Greenough series and the Harrington series were discussed from the point of view that the amount of irradiation was insufficient according to modern standards, which may be true. Answering the other question about the 17 to 20 per cent, it was based on the improvement of average results obtained throughout the country.

EFFECT OF GONADOTROPIC SUBSTANCE ON OVULATION

RESULTS OF THE INTRAMUSCULAR USE OF A PREPARATION OF HIGH POTENCY FROM PREGNANT MARE SERUM

JOHN I. BREWER, M.D., Ph.D.

HAROLD O. JONES, M.D.

AND

J. H. SKILES JR., M.D.

CHICAGO

A gonadotropic substance is one that stimulates the growth and hormonal function of the epithelial elements of the ovary.

Gonadotropic substances have been isolated from various fluids and tissues of the body, such as pregnancy blood serum, spinal fluid, castrate and postmenopausal urine, from the pituitary gland and from the placenta. They have been demonstrated to have two functions: one is stimulation of growth of the follicle and the other is the induction of ovulation and luteinization of the follicle. Gonadotropic substances vary considerably in their ability to stimulate the ovary. Although the characteristic activities have been demonstrated in experimental animals, results obtained with the use of these substances in the human female have not been as satisfactory.¹

Most of the reports indicate that of the many known gonadotropic substances, the one obtained from pregnant mare serum is probably the most effective in stimulating the human ovary. Reports that ovulation has been induced in the human being have been published.² Numerous clinical reports advocate the use of these substances in patients who present sterility problems, in patients with functional bleeding and amenorrhea. A critical survey of these reports leads to the conclusion that, in general, the clinical use of these substances has not been completely satisfactory. Many reasons may account for this. The effectiveness of a gonadotropic substance depends on the induction of ovulation and the maintenance of a normal functioning corpus luteum. It is apparent from the numerous reports that ovulation cannot be induced at will in a given patient. Second, failure of ovulation may not be the primary and essential defect in the endocrine physiology of a given person. Third, the dosage that will always induce ovulation in a given person has not been determined. The dosage requirements are undoubtedly not uniform in a single patient at various times in the cycle, and certainly they would not be uniform in different persons. Fourth, it is possible that failure may at times result from the injudicious choice of the route of administration of the substance. Intramuscular injections

may be unsatisfactory because of the lack of sufficiently potent preparations. Fifth, it is possible, as recent reports suggest, that the administration of a substance with a synergistic action is necessary to enhance the action of a single gonadotropic substance.³

Absolute proof that follicle stimulation, ovulation and luteinization have been produced in the human being by the injection of a gonadotropic substance is difficult to establish. It is essential that microscopic studies of the corpora lutea be made. Exact criteria must be known and accurately applied to determine the age of a given corpus luteum. Even if this is done and the accurately estimated age of a given corpus luteum coincides with the time elapsed between the injection and the surgical removal of the tissue, it is impossible to state with certainty that the medication induced ovulation and luteinization. It is possible only to infer that the ovulation resulted from the medication rather than that it was spontaneously present. Large series of patients must be studied and the corpora lutea must be studied histologically before such inferences could be of unimpeachable value. On the other hand, if the estimated age of the corpus luteum is greater than the time elapsed between injection and operation, it can be stated definitely that the ovulation was not experimentally induced.

Proof of the efficacy of treatment would be more absolute if ovulations could repeatedly be induced during the early and late phases of the menstrual cycle. This is true, since spontaneous ovulations, although they do occur early and late in cycle, are relatively infrequent at these times. Proof could be firmly established by inducing ovulation experimentally in a patient who had ovulated spontaneously and normally shortly before or after treatment. Thus corpora lutea of different ages would exist in the same patient and their respective degrees of development would lend themselves readily to the making of a positive statement that the treatment had produced one of them.

Another aid in the establishment of proof would be the repeated demonstration of superovulation (simultaneous ovulation of more than one follicle) completely beyond the realm of normal probability, both in number and in frequency. Here it rests with the individual author to establish without question of doubt that the multiple corpora lutea are normal and that they are not aberrant corpora, such as luteinized unruptured follicles. This is sometimes extremely difficult. It requires considerable effort and time, since serial section studies of the complete corpora lutea are necessary to permit one to say that ovulation has truly taken place and that an ovum is not imprisoned within. Identification of the stigma or ovulation point is fairly conclusive that ovulation has occurred. In many instances, however, the stigma may have healed and may not be readily discernible.

The fact that ovulation occurs in some patients with functional amenorrhea after treatment with gonadotropic substances does not prove the efficacy of the treatment. These patients are known to ovulate spontaneously. Thus, before claims can be made, one must induce ovulations in a sufficient number of patients to obviate the possibility of coincidence. Ovulation may occur spontaneously also in women during phases of

abnormal uterine bleeding. Conclusions must be drawn cautiously when ovulation is observed after injections of gonadotropic substances in such patients.

It is necessary that additional, exact, experimental evidence must be accumulated concerning the effectiveness of the gonadotropic substances in the human female before it is feasible to claim that these substances are of clinical value.

per cubic centimeter. One rat unit is the equivalent of 2 international units.⁷ In table 1 the varying dosages are shown. The lowest amount given to any patient in the series was 600 rat units. This is comparable to 60 Cartland units,⁸ used by Davis and Koff. The dosages ranged up to 5,000 rat units (10,000 international units) in divided doses. The largest single dose was 2,000 rat units.

This work was undertaken in an attempt to induce ovulation by using a more highly concentrated pregnant mare serum substance intramuscularly.

MATERIAL AND METHODS

The gonadotropic substance used in this experiment was obtained from pregnant mare serum by the Cole and Hart⁴ method of extraction and is known commercially as "gonadin."⁵ Two concentrations of the substance were used. One solution contained 200 rat units⁶ per cubic centimeter and the other 1,000 rat units

Intramuscular injections were used throughout. Davis and Koff stated they obtained much better results by intravenous injections. This work, therefore, is not identical to theirs, nor should the results presented here be confused in any way with the results of intravenous therapy.

The patients chosen were all to be operated on so that the ovarian tissues and the associated endometrial tissues might be available for microscopic study. The menstrual cycles were for the most part normal or near normal. However, a few patients who had abnormal

⁸ Cartland, G. E., and Nelson, J. W.: *J. Biol. Chem.* 110: 59 (June) 1937.

cycles were chosen in an effort to induce ovulation in the presence of abnormal uterine bleeding. Fifteen patients had normal cycles, 5 had menorrhagia, 2 had menorrhagia and metrorrhagia and 2 had metrorrhagia. One of the 15 patients with normal cycles was six weeks pregnant when she was operated on.

Fig. 1—Patient 5, operated on on the ninth day of her menstrual cycle, was given 800 rat units of gonadotropic substance twenty hours preoperatively. The corpus luteum, which is partly vascularized, is older than 20 hours.

It is apparent that these patients were operated on for pelvic disorders (table 1). It has been demonstrated, however, that pelvic lesions are frequently present in association with normal ovarian and endometrial functions.⁹ It is apparent, then, that ovulation, the development of the corpus luteum and the endometrial responses to ovarian stimulation may be normal in conditions similar to those for which the patients of this report were operated on. Therefore, while the patients studied were not ideally suited to a study of normal function, they were sufficiently suitable to warrant certain conclusions.

It is difficult to control experimental work of this type in the human being. In this work a control group of patients was studied. These patients were chosen because they were near the same age, had similar pelvic disorders and were operated on on the corresponding days of the cycles as patients of the treated group.

TREATED GROUP

Arrangement of the treated patients included in this report into subgroups is desirable for the convenience of study. The first group is composed of 12 patients operated on from the first to the fourteenth day of the menstrual cycle inclusive. The second such group comprises 11 patients operated on from the fifteenth to the thirty-fourth day of the cycle. One patient was operated on during pregnancy.

SUBGROUP 1.—Two of the 12 patients operated on in the first half of their menstrual cycle possessed corpora lutea of the current cycle (table 1). All had regressing corpora lutea of the previous cycle. Patient 5, operated on on the ninth day of her cycle, had two corpora lutea of the current cycle. The age of these corpora lutea is estimated at more than 24 hours and less than 48 hours (fig. 1). A single intramuscular injection of 800 rat units of gonadotropic substance was given twenty hours before operation. Since the age of the corpora lutea, as determined by histologic and cytologic methods, is greater than the time elapsed between the injection and the operation, it is obvious that ovulation in this patient had occurred prior to and was not due to the use of the gonadotropic substance. The endometrium was early secretory in character and was consistent with the degree of development of the associated corpora lutea. That ovulation may occur this early in the menstrual cycle is evidenced by a study of the control group as well as by a study of young human embryo material.

Advocates of the theory that the follicular phase of a given menstrual cycle may vary greatly in length but that the corpus luteum phase is more or less definitely fourteen days in length have support in the findings of this patient. Ovulation must have occurred on the seventh or eighth day of the cycle. If the corpus luteum phase is fourteen days, the onset of menstruation in this patient would be expected on the twentieth or twenty-first day of the current cycle. The menstrual history given by the patient was that she menstruated every twenty-one days for three days. Thus the findings and history correlate very well.

Fig. 2—Patient 12, operated on on the fourteenth day of her cycle, had two identical corpora lutea in the stage of bloom. The age is greater than 45 hours, which corresponds to the time preoperatively that the gonadotropic substance was given.

Patient 12 was operated on on the fourteenth day of her menstrual cycle. Two identical corpora lutea were present (fig. 2). The degree of development of the corpora lutea indicates that ovulation had occurred before the injections were given, since the gonadotropic substance (1,000 and 2,000 rat units) was given forty-

⁹ Sammartino, R., and Gandolfo Herrera, R. Rev. med. latinoam. 25:375 (Jan.) 1940. Brewer, J. I., and Jones, H. O. Am. J. Obst. & Gynec. 41:733 (May) 1941.

five and twenty-two hours preoperatively respectively. The endometrium is developed to a degree consistent with that of the corpora lutea.

In none of the other 10 patients was there any evidence of recent or induced ovulation. Patient 1 had two identical regressing corpora lutea of the previous cycle.

Fig 3—Patient 13, operated on on the fifteenth day of her cycle, possessed a corpus luteum in the bloom stage. The injection of the gonadotropic substance could not have induced ovulation, since it was given only forty-two hours before operation.

It is worthy of note that in 3 patients in this group (9, 10 and 11), operated on on the twelfth, thirteenth and fourteenth days respectively, ovulation had not occurred, either spontaneously or as the result of the intramuscular use of a gonadotropic substance.

SUBGROUP 2.—Of the 11 patients comprising this group 1 (20) had not ovulated spontaneously or as a result of the injections when she was operated on on the twenty-first day of her menstrual cycle (table 1). The other 10 patients possessed corpora lutea of the current cycle in various degrees of development.

Patient 13 was operated on on the fifteenth day of her cycle. The corpus luteum was older than the forty-two hours which elapsed between the injection and the operation (fig. 3).

Patient 14 had two identical corpora lutea which were in the vascularization stage and were obviously more than 25 hours old. Two thousand rat units of gonadotropic substance had been given twenty-five hours before the operation.

The corpus luteum of patient 15 was 3 to 4 days old, and, since the first injection of 1,000 rat units of gonadotropic substance was given ninety-six hours before the operation, it is probable that ovulation occurred within that span of ninety-six hours. That the injections induced the ovulation cannot be claimed or denied, since there is no possible way of proving it one way or the other. Ovulation could be expected to occur normally at this time in the cycle.

Patient 16, operated on on the twenty-first day of her cycle, had a corpus luteum in the stage of bloom that was considerably older than 96 hours, which corresponds with the time before operation that the first injection was given.

Patient 17 had a corpus luteum in the bloom stage and an endometrium that showed beginning involution. The latter is indicative of the onset of menstruation within two or three days. Thus it does not appear possible that ovulation had occurred within one hundred and twenty hours (five days) prior to the operation. The injected gonadotropic substance does not seem to have played a part in the process of ovulation in this patient.

In patient 18 injections of the gonadotropic substance were begun three hundred and twelve hours (thirteen days) prior to the operation, which was performed on the twenty-first day of her cycle. A study of the two identical corpora lutea indicated that ovulation had occurred within this thirteen day span. Again, however, one cannot claim or deny the effect of the injected material on the ovaries.

Patient 19 was operated on on the twenty-first day of her cycle. The corpus luteum was in the stage of bloom and the endometrium was secretory in character. The age of the corpus luteum is greater than the forty-five hours elapsing between the first injection and the operation. This fact indicates that ovulation did not result from the medication.

The corpus luteum of patient 21, operated on on the twenty-seventh day of her cycle, was in the late bloom stage and the endometrium showed involution and early menstrual changes. Ovulation in this patient had undoubtedly occurred more than one hundred and sixty-eight hours (seven days) prior to the operation.

Patient 22 was operated on on the twenty-eighth day of her cycle. The corpus luteum was in the late bloom stage. The endometrium had undergone involution.

Fig 4—The corpus luteum removed from patient 23 on the thirty-fourth day of the cycle was in the stage of bloom. It is not probable that the gonadotropic substance given ninety-six hours prior to operation had induced ovulation in this instance.

Since the gonadotropic substance was given only sixty-eight hours prior to operation, it is obvious that it played no part in the process of ovulation in this patient.

Patient 23 had menstrual cycles of twenty-eight days' duration, but the current cycle had lasted thirty-four days when she was operated on. Injections of the

gonadotropic substance were begun ninety-six hours prior to operation. The corpus luteum was in the bloom stage (fig. 4) and the endometrium was correspondingly developed. It is not probable that the gonadotropic substance was important in inducing ovulation in this patient.

Patient 24 was operated on at six weeks of pregnancy. No new corpora lutea were present. A single injection of 600 rat units of the gonadotropic substance was given sixty-nine hours before operation.

In most instances there was increased vascularity and, in some instances, hemorrhages in the ovarian tissues,

particularly about the larger follicles but also about the corpora lutea. Similar hemorrhaging has been reported to occur in the ovaries of the human being and the monkey following gonadotropic therapy. Increased follicle atresia and degenerated changes in follicles were not observed.

CONTROL GROUP

The control group comprises 22 patients whose ages, menstrual histories and pelvic disorders approximate those of the experimental group as closely as possible (table 2). Ten of these patients were operated on on or before the fourteenth day of their menstrual cycle. Two patients (2 and 5) had twin corpora lutea in the regression phase that were no doubt formed in the preceding cycle. They were operated on on the second and eleventh days, respectively. One patient (6) operated on on the eleventh day had a young corpus luteum whose degree of development indicated that ovulation

had occurred on the ninth or the tenth day. Three other patients on the thirteenth and fourteenth cyclic days possessed young corpora lutea.

All 12 patients operated on on or after the fifteenth cyclic day had normal corpora lutea. One patient (22) was operated on on the thirty-ninth day of her cycle. In this patient the development of the corpus luteum, which was in the vascularization stage, indicated that ovulation had occurred spontaneously about the thirtieth day.

COMMENT

In the treated group of 24 patients, 13 possessed corpora lutea of the current cycle. This number includes the 1 patient who was pregnant and who possessed a normal corpus luteum of pregnancy. A microscopic study of the corpora lutea of 11 of these 13 patients indicates definitely that ovulation could not have occurred as a result of the intramuscular injection of the gonadotropic substance. The estimation of the ages of the corpora lutea and the duration of time elapsing between the injections and the surgical removal of the corpora lutea were used as the basis for this statement. In 2 instances (patients 15 and 18) ovulation undoubtedly occurred within the time limits noted. This fact alone, however, cannot be construed to mean that the ovulation resulted from the medication. It is most probable that ovulation would have occurred spontaneously in these 2 patients at this time in their cycles regardless of the medication.

In the control group of 22 patients, 16 patients possessed corpora lutea of the current cycle. This compares favorably with the 13 patients with corpora lutea in the treated group. This comparison is significant, since approximately an equal number of patients of each group were operated on in the first and last halves of the menstrual cycle. There was no demonstrable increase in the incidence of ovulation in the treated group. The number of patients studied is too small to permit definite conclusions, but the consistent results merit some value.

Ovulation was not induced in the treated patients either early or late in the cycle. In 2 patients (5 and 12) ovulation had occurred early in the cycle (table 1), but in both the ovulation was spontaneous. In the control group 1 patient (6) had ovulated at a similar early period (table 2). Ovulation relatively late in the cycle was observed in 1 patient of the treated group (23), but here again it was undoubtedly spontaneous. That ovulation does occur late in the cycle is an established fact and is well borne out by the observation on 2 patients (21 and 22) in the control group who ovulated late in the cycle.

The simultaneous induction of ovulation of more than one follicle was not brought about as a result of the therapy. Four patients in this group of 24 treated patients had simultaneous ovulations of two follicles in the current cycle. In only 1 patient (18) did the bare possibility exist that the gonadotropic substance induced the ovulation. This single instance cannot be considered too strongly in an evaluation of the effectiveness of the treatment. In 1 patient (1) double ovulation had occurred in the preceding cycle. In no instance was superovulation induced beyond the realm of normal probability. Two simultaneous ovulations were the greatest number observed. In the control group of 22 patients, two identical corpora lutea of the current cycle were present in the ovaries of 1 patient. Double ovulation had occurred during the immediately previous cycle in 2 patients (2 and 5). The similar frequency of

double ovulations in the patients of the control group and the treated group makes it seem likely that the incidence in the treated group was a matter of coincidence rather than a result of treatment.

An attempt failed to induce ovulation before or after spontaneous ovulation. In the ovaries of no patient were there corpora lutea of different ages or degrees of development.

In the control group no patient operated on after the thirteenth day had failed to ovulate spontaneously, whereas in the treated group 1 patient operated on on the thirteenth day, 1 on the fourteenth day and 1 on the twenty-first day had failed to ovulate either spontaneously or as a result of the injected gonadotropic substance. This again is undoubtedly a matter of coincidence and without significance with respect to the treatment received. It cannot be concluded that the treatment in these particular patients prevented ovulation.

Adhering strictly to the criteria and the ideal conditions elaborated on, which are necessary to establish absolute proof that ovulation has been induced in the human being by a gonadotropic substance, we must state that ovulation was not induced in the patients of this report. In no respect can conclusions be drawn from the results of this report concerning the effects of gonadotropic substances administered intravenously as reported in the literature.

Since little is known concerning effective dosages of gonadotropic substances, it is possible that in this work the correct, effective dose was not given at the correct time. This might account for the failure to induce ovulation. It has been stated that large dosages produce luteinization of unruptured follicles but will not induce ovulation. In the specimens of this study luteinization of follicles beyond normal was not present. This suggests that the dosages were not too large.

CONCLUSIONS

1. Intramuscular injections of a pregnant mare serum gonadotropic substance of high potency failed to induce ovulation in 22 of the 24 patients studied. In the other 2 patients it is impossible to prove or disprove that ovulation occurred as a result of the injected substance.

2. Multiple ovulations were not induced.

3. No new ovulation superimposed on spontaneous ovulation was induced.

4. Ovulation occurred more uniformly in the 22 patients of the control group than in the 24 patients of the treated group.

Yellow Fever.—The first recognized account of yellow fever is that given by Père Jean Baptiste Du Tertre (1667-1671) of the outbreak which he himself witnessed in the island of Guadeloupe in 1648. A few months later, Diego Lopez De Cogulludo (1688) described an epidemic with similar characteristics in Yucatan. Since Carter (1931) published his epidemiologic and historical study of the place of origin of yellow fever, much has been learned not only of the nature of the disease but of the circumstances attending the outbreak of yellow fever in 1648. These observations are in favor of the view that infection was brought to the West Indies from the West Coast of Africa, either to Barbados or less probably to St. Christopher, whence it spread to Yucatan and to Havana.—Findlay, G. M.: *The First Recognized Epidemic of Yellow Fever*, *Tr. Roy. Soc. Trop. Med. & Hyg.*, November 1941, page 143.

A COMPARATIVE APPRAISAL OF THREE CONTRACEPTIVE SERVICES

REGINE K. STIX, M.D.

NEW YORK

Obstetricians, gynecologists and public health officers agree that the woman with serious systemic disease who becomes pregnant, when pregnancy constitutes an additional health hazard, contributes heavily to maternal morbidity and mortality. In advising his patients about the prevention of pregnancy, however, the physician is somewhat hampered by the fact that, because of inadequacies in the statistical techniques used, much of the published material in the field of contraception has failed to give a reliable comparative evaluation of the effectiveness and acceptability of available methods.¹ In most instances, therefore, physicians have confined their advice on contraception either to blanket advice "not to become pregnant" or to the prescription of the occlusive diaphragm with jelly, a method which has been almost universally prescribed in contraceptive clinics.

In an attempt to learn just how various types of people have been served by existing contraceptive services and to evaluate the relative effectiveness of various contraceptive techniques, three studies of contraceptive clinics in different sections of the United States have recently been completed by the Milbank Memorial Fund. One, the Birth Control Clinical Research Bureau (now the Margaret Sanger Research Bureau of the Birth Control Federation of America), is in New York City. The other clinics are both independent of the Birth Control Federation. One, the Cincinnati Maternal Health Clinic, operates under the supervision of the local Academy of Medicine; the other is a referral service in the Spartanburg General Hospital in Spartanburg, S. C., and is a regular clinic of the Spartanburg County Department of Health.

THE RECORDS USED FOR STUDY

The records and methods of study differed slightly for the three clinics, but essentially the same information was available for the families in all three regions. In New York, 991 women from the Bronx who attended the clinic between Jan. 1, 1931 and June 30, 1932 were interviewed in their homes by me between one and two years after their initial contact with the clinic.¹ In Cincinnati, 1,621 women who had attended the clinic in the five years between its inception in November 1929 and Dec. 31, 1934 were interviewed in their homes by a trained nurse in 1935 and 1936.² In Spartanburg, detailed records were secured for the first 990 patients attending the clinic, which opened in July 1935.³ Complete follow-up records were kept as patients returned, while for those who failed to return in 1939 and had not moved away the records were completed by means of home visits.

Each record contained social and economic information and a complete and detailed fertility history for the period between marriage or first coitus and the date of interview. It included the date and type of termination of each pregnancy, information concerning any morbidity associated with it, and data on the use of contraception which preceded it. In New York, medical

information was limited to that elicited for the fertility history. In Cincinnati, each record included a brief medical history and data on the pelvic examination given the patient on her initial clinic visit. In Spartanburg, the method of referral permitted the inclusion of detailed information from the pelvic examination given each patient, the diagnosis made at the referring clinic and the results of laboratory procedures, which included a blood test for syphilis, cervical and urethral smears and a urinalysis.

THE PATIENTS OF THE THREE CLINICS

The patients of the three clinics were very different. The women who attended the Clinical Research Bureau, in New York City, were mainly foreign-born Jewish women from families with moderate incomes. Most of them came to the clinic on their own initiative and paid for the service given them. In Cincinnati, most of the patients were relief recipients or wives of manual workers with small incomes who, because their families were large and the mothers needed to be spared the burden of additional pregnancies, were referred for contraceptive advice by social workers or physicians. The patients selected for study in New York City and Cincinnati were all white women; in Spartanburg, however, nearly half were Negroes. The Spartanburg clinic serves women from rural and urban sections of a Southern cotton county. Its patients are sent to the clinic mainly because of illness contraindicating further pregnancy. Those referred during the period of study were the wives of urban manual workers, of sharecroppers and of farm tenants, whose economic status was very low.

The outstanding differences between the patients in the three areas are evident in the reasons for their seeking contraceptive advice. The New York women were concerned about controlling their fertility and were

before they attended the clinics, are shown in chart 1.⁴ These rates show the usual economic, social and regional differentials. The Spartanburg Negroes had the highest birth and pregnancy rates, the New York clinic patients the lowest.

Chart 2.—Proportions of couples in three areas who were using contraception at various periods before the wives attended a birth control clinic.

Chart 1.—Pregnancy and birth rates per hundred women for four groups of women prior to clinic attendance (rates standardized for age).

It is well known that the most important factors associated with group differences in fertility are differences in the prevalence and effectiveness of contraception and in the extent of illegal abortion.⁵ In order to determine the influence of these factors in the experience of the women under consideration, it is necessary first to determine what differences there were in the rates at which they conceived during those periods when there was no attempt to use contraception.

The mean number of months of exposure to the risk of pregnancy for each pregnancy experienced is a measure of the average frequency with which women in the three areas conceived.⁶ When no attempt was made to use contraception, the New York women conceived much more rapidly than the women in any of the other groups. The Cincinnati women, in turn, conceived more rapidly than either group of Spartanburg women (table 1). The first pregnancies of women in New York who used no contraception were conceived about four months after marriage. For the other groups the interval was nearly twice as long. After the first pregnancy the average period free of pregnancy for each pregnancy experienced was considerably longer for all

willing to pay for expert contraceptive advice. The women in Cincinnati and Spartanburg were referred for advice mainly because their physical condition or economic circumstances contraindicated further pregnancy, at least temporarily.

The birth and pregnancy rates per hundred women of the three groups of white and one of Negro women,

4. The rates are standardized to the age distribution of all married women 15-44 years of age in the 1930 census. Women under 15 and over 44 years of age were excluded from the tabulations.
5. Pearl, Raymond: *The Natural History of Population*, New York, Oxford University Press, 1939, p. 244. Stix and Notestein: *Stix*.
6. Exposure to the risk of pregnancy covers that period of a woman's life between menarche and menopause during which she is habitually indulging in coitus, as in marriage, and is not pregnant. The mean number of months of exposure was derived by dividing the aggregate number of months of exposure by the number of pregnancies occurring in the exposure. See also Stix and Notestein: *Controlled Fertility*, pp. 113 and table 16.

groups. The group differences for the later pregnancies were smaller than for first pregnancies, but the intervals were shortest for the New York group and longest for the Spartanburg women. It is obvious, therefore, that the high pregnancy and birth rates of the Southern women were not associated with "biologically superior" uncontrolled fertility.

The group differences in uncontrolled fertility may be attributed mainly to two factors: the first, a tendency toward prolonged lactation among the Spartanburg women, and the second, the fact that the types of pathologic condition which might be expected to interfere with fertility were least prevalent in New York and most prevalent in Spartanburg. In all three areas the women with evidence of pelvic infection, endocrine disease or syphilis conceived much less rapidly than women free from pathologic conditions.⁷

The differences in the total preclinic fertility of the four groups under discussion could in no way be considered due to differences in "biologic capacity," because the group with the lowest birth rates had the highest uncontrolled fertility and the groups with the highest birth rates the lowest uncontrolled fertility. The differential prevalence and effectiveness of contraception are, therefore, the next factors to be considered.

The periods at which couples first turned to the use of contraception differed in the three areas (chart 2). The New York couples used contraception earlier and more extensively than any of the others. About 85 per cent of them had started to use contraception before the wives became pregnant for the second time. Only 25 per cent of the Negroes had ever used contraception before they attended the maternal health clinic.

During their use of contraception each group of women conceived much less rapidly than when no contraception was used. The average period free from pregnancy for each pregnancy experienced was much longer for each group than the average period when no contraception was used (table 2). For women using contraception from marriage, the mean number of

from twenty-one months for Negroes to nearly four years for the New York women.

In New York the use of contraception prevented 79 per cent of the pregnancies that would have occurred if the women had used no contraception for an equal period of exposure; in Cincinnati its use reduced the risk of pregnancy by 52 per cent; among the Spartan-

burg white women the reduction was 47 per cent, and among the Negro women 28 per cent (table 3).

These differences in effectiveness were due partly to a variation in the types of contraception used in each area and partly to differences in the effectiveness with which each type was used. Table 4 shows the distribution, in the total exposure with contraceptives, of the types of contraception used by each group, and table 3 the effectiveness with which each of the three most commonly employed methods reduced the risk of pregnancy for each group of women.

The condom and coitus interruptus were the methods most frequently used by the white couples in all three areas. The most frequent choice of the Negro couples was the douche. The New York couples used each contraceptive with much greater effectiveness than any of the other groups.⁸ The effectiveness of the condom was high both in Cincinnati and in New York. In Spartanburg, however, its use reduced the risk of pregnancy for the white women by only 50 per cent. Because most of the Spartanburg couples who used condoms found them too expensive to use regularly, the periods of reported condom use include, in many cases, only sporadic use of the contraceptive. The effectiveness of both coitus interruptus and the douche was fairly high for the New York couples but quite low in both Cincinnati and Spartanburg.

In addition to the differences in the prevalence and effectiveness of contraception in the preclinic experience of the four groups of women under consideration, differences in the proportions of their pregnancies terminating in live births had a definite influence on their birth rates (see solid bars in chart 1). Chart 3 shows, for each group of women, the proportions of pregnancies terminating in live births, illegal abortions and other pregnancy wastage.⁹ Nearly one fourth of the pregnancies of the New York women were terminated by illegal abortion. Only 8 per cent of the pregnancies of the Cincinnati women and less than 1 per cent of the

8 Experience with contraceptives, for all the groups under consideration, includes all attempted use of contraception. If some members of a group used a contraceptive only sporadically, their experience was included in the group exposure with that contraceptive. See also Stix and Notestein, *Controlled Fertility*, p. 121.

9 Stillbirths, spontaneous abortions and therapeutic abortions.

pregnancies of the Spartanburg white women were so terminated. There were almost no illegal abortions among the Negro women; they had a high rate of stillbirth and spontaneous abortion, however, because of the high prevalence of syphilis in the group.¹⁰ For the white

Many of them lived in crowded homes under conditions which made the regular use of any contraceptive extremely difficult. In addition to furnishing them with effective contraceptive technics, the Cincinnati clinic had the responsibility for educating many of them to the regular use of contraception.

These problems were intense for the Cincinnati clinic had an even greater. Few of the patients had ever used effective contraception. In almost half the cases serious illness made further pregnancy dangerous to the life and health of the mother. Social and economic handicaps were even greater for these women than for the Cincinnati patients. It was imperative that they learn to use contraceptives consistently and effectively if they were to be spared the hazards of serious illness or death.

† Insufficient exposure.

women in all three areas the proportion of pregnancies terminating in stillbirths and spontaneous abortions ranged between 8 and 12 per cent. For the Negro women it was 16 per cent.

This analysis of the factors associated with the differences in the preclinic fertility of four groups of birth control clinic patients shows the results of differences in the attitudes of these women toward the problem of controlling their fertility. Such attitudes should determine to a great extent the policies of the clinics from which they seek advice.

The New York women who came to the Clinical Research Bureau were thoroughly familiar with a number of contraceptive technics, and as a group they had used them with considerable effectiveness. It was quite unnecessary to educate most of them to the use of contraception. They sought and obtained advice on

technics which would presumably be more acceptable to them than the contraceptives they had used previously.

Commercial contraceptives were less accessible to the women who attended the Cincinnati Maternal Health Clinics than to the New York patients because most of them were too poor to buy reliable contraceptives.

10. Thirty-one per cent of the Negro women had positive Wassermann and/or Kahn reactions. For proportions of pregnancies terminating in stillbirths and spontaneous abortions for the Negroes with syphilis, as compared with those without, see Stix: *Syphilis and Uncontrolled Fertility*, table II.

THE CLINIC SERVICES AND THE MEASUREMENT OF THEIR EFFECTIVENESS

The policies of the three clinics were alike in that an occlusive rubber device, usually a diaphragm, and jelly

to be used by the wife, were prescribed for 90 per cent or more of the patients of each clinic (table 5). Contraceptives of this type have usually been considered the only methods suitable for prescription. The use of a contraceptive involves highly personal problems, however, and it seems unlikely that a single type of contraception could be acceptable to all the couples for whom it is prescribed. For this reason the wisdom of such a single minded policy, which makes little or no allowance for individual or group differences, is open to question.

In order to ascertain the results of these policies, it is necessary not only to know the effectiveness of the prescribed technics in preventing pregnancy for those women who use them but also to learn how many patients never use the prescribed contraceptives, how many continue to use them for as long as their experience is known and how many use them and then give them up. It is also important to know about the subsequent practice of couples who reject the prescribed technics.

In all three of the areas under consideration, the contraceptives prescribed by the clinics proved highly effective. For those patients who used them, the prescribed contraceptives reduced the risk of pregnancy by between 80 and 94 per cent (table 6). The ratios of effectiveness were lowest for the Spartanburg women and highest for the New York clinic patients. It is not

surprising that the Spartanburg patients were less skillful in using the diaphragm than the average patient in New York or Cincinnati. The effectiveness with which it was used in Spartanburg was approximately the same as that observed for relief recipients in Cincinnati.¹¹ It is probable that women in both groups were not only handicapped by the conditions under which they lived but were also poorly equipped by education and intelligence to use a complicated contraceptive technic consistently and correctly.

Not all women were willing to use the prescribed contraceptives. Table 7 shows the proportions of women in each group of clinic patients who never used them, who used them for a time and then discarded them and who were using them at the time they were interviewed. In spite of a longer average postclinic period in Cincinnati, with a correspondingly greater opportunity for the rejection of the prescribed methods, the proportions of women using the prescribed contraceptives in any form when their records were closed were significantly higher in both Cincinnati and Spartanburg than in New York.¹²

The differences between the New York and the Cincinnati patients were even greater when the proportions using the prescribed contraceptives at equal intervals

Chart 3—Proportion of pregnancies terminating in live births, illegal abortions and other pregnancy wastage for four groups of women prior to clinic attendance

following the initial clinic contact are compared. Chart 4 shows, for the four groups, the proportions of women still in need of contraception who were using the prescribed contraceptives at successive intervals during the first year following their initial contact with the clinic. In all three clinics the most rapid loss of patients occurred within a brief period after the first clinic contact. A year after they had first sought expert contraceptive advice, the proportions of women in the three areas who were using the contraceptives given them ranged between about 55 per cent for the New York patients and for the Spartanburg Negroes, and 68 per cent for the Cincinnati women. Had it been possible to compute similar figures for the lost as well as for the interviewed patients, the proportions using the methods advised would have been considerably lower for all groups.

A variety of reasons were given for the rejection of the prescribed methods, but it should carry considerable weight with physicians and clinic administrators that

30 per cent of the New York women, 24 per cent of the Spartanburg Negroes and about 20 per cent of the women in each of the other groups gave up the diaphragm because it was uncomfortable, difficult to place, esthetically unacceptable or too much trouble to use.

TABLE 6—Per Cent of Effectiveness of Each Type of Contraception as Used by Four Groups of Women After Clinic Attendance *

after the wives had been advised at the clinics. The proportions using no contraception either throughout the postclinic period or after they had given up the clinic prescription were very low in New York and Cincinnati and very high in Spartanburg. Thirty-nine per cent of the Negro and 23 per cent of the white women in Spartanburg had given up any attempt to use contraception by the time their records were com-

11 Stix: Birth Control in a Midwestern City, table 22.

12 The data for all three clinics relate only to those patients who could be found and interviewed between one and five years after their initial contact with the clinic. It may be assumed that those women who failed to maintain contact with the clinics and therefore could not be found were probably not using the contraceptives prescribed for them. For a detailed discussion of the possible bias introduced by the loss of between 15 and 20 per cent of the patients originally in each sample, see references 1, 2 and 3.

pleted. Only 2 per cent of the women in Cincinnati and only 3 of the 991 women in New York did the same. In New York 60 per cent and in Cincinnati 46 per cent of the couples turned to the use of other types of contraception, mainly those with which they were already familiar. Only 20 per cent of the white and

groups of patients studied were typical of the widely differing groups served by physicians and clinics in various sections of the country. The New York group was probably more nearly like the patients of the average urban physician in private practice than like the patients of other clinics. The methods prescribed at the clinic were very satisfactory for some of the patients. The patients who were dissatisfied with the clinic prescription, however, should have been taught the best use of those technics which they preferred. A detailed analysis of their reactions suggested that a more flexible policy, permitting the prescription of a wide selection of generally used technics, would probably have been more satisfactory to the patients.¹³

The patients of the Cincinnati clinic were probably representative of the average urban maternal health clinic clientele. For this group also the clinic should have offered a wider choice of contraceptive technics. The cost of commercial contraceptives may have prevented the use of the more effective methods, such as the condom, by many couples who did not like the diaphragm and jelly. For those couples who were not on relief, the condom ranked high among alternative methods, but couples on relief depended mainly on coitus interruptus or the douche. Had the clinic provided a variety of methods at little or no expense, the service might have been considerably more effective.

The patients of the Spartanburg clinic are typical of women of low economic status in Southern areas of population pressure. The surprising finding for this

Chart 4.—Proportions of clinic patients using the prescribed contraceptives at successive intervals following their initial clinic contact.

10 per cent of the Negro couples in Spartanburg, who had had much less previous experience with contraception, attempted the use of contraceptives other than those prescribed.

In New York and in Cincinnati the contraceptives most frequently used by couples who decided against using the clinic prescription were coitus interruptus and the condom, in the order named (table 9). In Spartanburg these were also the methods of choice of white couples but in the reverse order. Fifty-six per cent of the Negro women who preferred other contraceptives to those prescribed at the clinic used the douche.

All contraception was more effective after clinic attendance than before for the patients of all three clinics. The percentage of increase in the effectiveness of contraceptive practice after the women had been advised at the clinics is shown in chart 5. For the New York women the postclinic effectiveness of all contraceptives, including those prescribed, was only 18 per cent greater than before clinic attendance, because their preclinic use of contraceptives was so effective that there was little opportunity for improvement. For Cincinnati women the increase was 63 per cent and for Spartanburg white women 72 per cent. For the Negro women, whose preclinic contraceptive practice had little effect on their fertility, the increase was 179 per cent. Even when experience with the prescribed contraceptives was excluded, increases in the effectiveness of other types of contraception ranged from 15 per cent for the New York patients to 96 per cent for the Spartanburg Negroes.

The findings of the studies summarized in this report have important implications for policy, because the four

group is that so many patients were willing to use a complicated contraceptive technic in spite of inadequate education and poor housing. It is probable that many women who realized the hazard of an additional preg-

nancy made a special effort to prevent the occurrence of such a pregnancy. For the couples without funds, the methods prescribed at the clinic and those which required no expenditure of money were the only ones available.

It is obvious that a contraceptive service for a group such as that attending the Spartanburg Maternal Health

Of the three clinics selected for the present study, the one in Spartanburg is best designed to meet the medical needs of the patient for whom pregnancy would constitute a health hazard. Its interrelationship with the referring services in the hospital permits the best care of the patient from all points of view. An attempt is made to educate the patient who is referred for contraceptive advice to understand the importance of avoiding pregnancy until the referring physician advises her that pregnancy may be safely undertaken. In the repeated pelvic examinations made at the clinic, conditions are frequently found which justify referring the patient for types of medical care other than those for which she is already under supervision.¹⁴ It would seem highly desirable that, with the limited funds available, all subsidized clinics be under hospital or public health supervision in order that the patients in most urgent need of contraceptive advice may be the ones to use such services.

Among the significant and unexpected findings of the present studies has been the discovery that untutored methods of contraception are used quite extensively and with a considerable degree of effectiveness even by those groups who, for one reason or another, are referred for expert contraceptive advice. The effectiveness of contraceptive practice in large groups of people, unselected with respect to overt fertility or a special interest in controlling it, is as yet unknown, but it is certain that vast numbers of people in this country use contraception and probably do so with a fair degree of success.

For medically supervised contraceptive services, as well as for the protection of the mass of the population using commercial contraceptives, it is important that one of the recommendations of the Committee to Study Contraceptive Practices of the American Medical Asso-

Clinic is one which presents special problems. The ideal service for a group of such low economic and social status should offer a choice of very simple contraceptives requiring as little forethought and care as possible. The so-called "simple" feminine technics usually prescribed are cumbersome, however. For example, the Spartanburg clinician reports that few patients are willing to use the sponge and foam powder because they find it uncomfortable and just as difficult to use as the diaphragm, and they have less confidence in it. The very fact that nearly half of the 90 white couples using other types of contraception after they attended the clinic used condoms (table 9) is probably an indication that this method should have been prescribed more frequently.

If patients are willing to use the diaphragm and jelly or a similar technic, it has definite advantages over male technics in that it puts the control of fertility into the hands of the wife whose health is at stake. If that technic is not acceptable, however, every effort should be made to substitute another and preferable contraceptive which the couple can use effectively. It must be stressed repeatedly that the use of contraception involves many personal problems and adjustments. A method which may be relatively ineffective for some couples may be highly effective for the couple to whom it is acceptable and who use it with care and diligence, whereas even a highly effective method is of little or no use to the couple who dislike it and will not use it consistently. The solution of the problem may be more difficult in a rural Southern area than in a city such as New York, because fewer patients will have used any contraceptives previously and there will be less opportunity to encourage the best use of familiar technics. The wise policy for every physician and clinic, however, is to make sure that every couple is given the contraceptive or contraceptives best suited to individual needs and preferences and to educate each patient to return for further advice if the methods first prescribed are unsatisfactory.

ciation be put into effect as soon as possible. In its report to the Association in 1937 the committee recommended "that the American Medical Association undertake the investigation of materials, devices and methods recommended or employed for the prevention of conception, with a view to determining physiologic, chemical and biologic properties and effects, and that the results

14 Stix, Regine K. Gynecological Case Finding in Maternal Health Clinics, Milbank Memorial Fund Quarterly 19: 36 (Jan.) 1941.

of such investigations be published for the information of the medical profession.¹⁵

If the American Medical Association would set up standards for contraceptives as it has for drugs and foods, much could be done to improve the quality of commercial contraceptives. Wise pressure on commercial distributors to bring the price of approved products down to a point at which wider distribution would pay for decrease in price would probably make it possible for many people in the poorer sections of the country, where birth rates are highest, to purchase contraceptives not now available to them and would assist in reducing birth rates for that part of the population least able to bear the cost of rearing and educating large families.

THE COLOSTOMY QUESTION

LOUIS J. HIRSCHMAN, M.D.

DETROIT

One of the greatest boons to the patient suffering from a major obstruction or malignant disease of the colon, particularly the left half of this viscus, is the hope of either permanent cure or prolonged comfort provided by an artificial stoma. Almost every intestinal surgeon and proctologist has studied the problem of providing a satisfactory colostomy, with special reference to some form of bowel control.

Practically every portion of the abdominal wall and the perineum has been utilized for the location of the stoma. The number of different types of colostomies and the ingenuity expended in their formation would make exceedingly interesting and intriguing surgical history. The number of names attached to different types of colostomies resembles a roll call of most of the pioneers in intestinal surgery.

Every surgeon or proctologist operating on a diseased colon has been hopeful of supplying a type of colostomy which would satisfactorily exclude the diseased portion as well as substitute a well functioning artificial anus for the natural aperture. The ideal colostomy should be one formed well above the affected segment of the bowel. Whether this colostomy is to be a temporary or a permanent one will often affect the surgeon's or proctologist's decision as to its location.

When one wishes to divert the fecal stream temporarily, as in the treatment of nonmalignant diseases amenable to resection and anastomosis such as deformities, segmental polyposis or complicated multiple fistula, a double barreled colostomy is of course indicated. A double barreled colostomy may also be advisable as a permanent colostomy in patients suffering from inoperable and irremovable malignant growths and in patients whose general physical condition is precarious and in whom haste is an imperative factor.

The temporary or double barreled colostomy is of necessity an abdominal colostomy. In most instances some portion of the transverse colon is utilized for this purpose. The subsequent closure of a temporary colostomy of the transverse colon is a comparatively simple procedure. One has the advantage of omental utilization for added safety. Not infrequently the descending and also the upper portion of the sigmoid colon has been employed for temporary colostomy, and when there is

sufficient mobilization there is no reasonable objection to it.

In the fulguration of polyps in the upper part of the sigmoid colon a temporary sigmoidal colostomy is of distinct advantage. There is really nothing of a controversial nature about the location of a temporary colostomy.

When it comes to the site of a permanent colostomy, particularly in a patient afflicted with a malignant condition of the anorectal canal, rectosigmoid or the lower part of the sigmoid flexure, there are several factors which must be considered. The first of these is the selection of a section of the colon at least 6 inches above the upper limit of the neoplasm.

Naturally, in the minds of the majority of surgeons the extent of the growth, if not its grade, and the possibility of its complete excision with the least hazard are the prime factors. A patient's life is to be saved or prolonged, obstruction relieved and intestinal function restored to as complete a degree as is compatible with safety in the case at hand.

After the routine study of the patient, and after proctoscopy and sigmoidoscopy have been performed, the roentgenologic examination is of great importance. Fluoroscopic examination, with manipulation of the barium-filled colon, will often decide the type of colostomy to be performed. If the sigmoid flexure is long, redundant and freely movable above the neoplasm, greater latitude in the choice of the colostomy site is afforded the surgeon.

While the presence and extent of hepatic metastasis is an important guide in the prognosis of a patient suffering from a malignant growth in the colon, this should not necessarily influence the location of a permanent colostomy. If the colostomy is to be the best possible substitute for the normal anus and rectum, it should be located at a site in which it can function and be cared for by its possessor with the least amount of discomfort and embarrassment, either physical or mental.

Naturally, when one has been accustomed to normal defecation from a normal perineal anus in the normal sitting position, the news that relief from disease will require a complete change in the mode of intestinal evacuation comes as a psychic shock to even the most phlegmatic and philosophic person.

The great majority of those of us dealing with malignant conditions of the large bowel feel that an abdominal colostomy, with complete eradication of all affected tissue below the colostomy, is, in the present state of our knowledge, the best treatment there is to offer. When such a colostomy is to be performed, there are many arguments by many surgeons as to why various quadrants of the abdomen are utilized as a permanent colostomy site. It seems to me that the mental as well as the physical comfort of the patient should be considered along with the anatomic results to be achieved.

After observation of the discomfort and local irritation which some patients have suffered from a low left inguinal colostomy, the question has arisen Why continue to use this site? Whether one wears a cup, a cap, a dome, a bag or simple gauze pads there is a lack of symmetry to the patient's contour which violates his personal privacy by announcing to the world that there is "something wrong in Denmark." This is more noticeable, of course, in men than in women but is definitely of moment to both sexes.

While speaking of the type of protective covering for a colostomy, through the suggestion of one of my

15. Minutes of the House of Delegates, J. A. M. A. 108:2218 (June 26) 1937.
Read before the Section on Gastro-Enterology and Proctology at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 5, 1941.

patients, I have adopted a simple procedure. The metal ring and band of the Brick apparatus is utilized. However, instead of employing the now discarded rubber colostomy bag, a simple and inexpensive cover has been suggested.

Fig. 1.—Patient lying on left side. Single barreled umbilical colostomy.

I instruct my patients to purchase from the 5 and 10 cent store some of the waterproof elastic covers used for cups and small bowls to be placed in the refrigerator. These are so inexpensive that they can be discarded after use. The patient is instructed to place a small wad of absorbent cotton over the colostomy to act as a muffler for gas and also to absorb liquid. This device does not occupy as much space as the usual colostomy cap, cup or dome and is certainly less conspicuous under the clothing.

From the standpoint of the strength of the abdominal wall and the presence of a natural opening, well supported by muscular structures, the umbilicus offers many advantages as a colostomy site.

On account of its central location, any portion of the right and median colon ordinarily utilized for colostomy purposes can be brought out through an opening made by excising the umbilicus. Here, it is especially well supported by its adhesion to the thick rectus muscles which closely hug it at this point. Even a temporary colostomy at this site is well out of the way if a second stage abdominoperineal resection is to be performed.

In those rare instances in which, for some reason or other, the colostomy is not placed exactly at the umbilical opening but close to it, the umbilicus itself is always excised. This is done because fecal matter from the colostomy will enter and soil the umbilicus, and the patient's efforts to cleanse this area often result in trauma, erosion and infection.

A curved Pfannenstiel incision allows the skin flap to be raised upward in such a way as to give better

exposure for the resection in the lower part of the abdomen than is usually obtained by the midline or rectus wounds. Any dressings or colostomy apparatus that may be required is so centrally placed that bodily symmetry is preserved.

As the patient sits on the toilet, he holds a crescent basin underneath the colostomy while he injects, with a hand syringe, water necessary to prime the colostomy if and when movements do not occur spontaneously at least daily.

In emaciated patients, this location is a decided advantage over a site in the lower inguinal region because of the fact that a prominent anterior ischial spine not infrequently becomes eroded by irritation from feces or a bandage. The mobility of the sigmoidal segment selected for an inguinal colostomy is sufficient to allow the same portion of the colon to be swung upward to the umbilical site as well as downward in the left lower quadrant.

There is no reason why as much bowel, with as many metastatic glands, cannot be removed with the establishment of an upper midline colostomy as with the inguinal site on the left side. As has been mentioned, the same portion of sigmoid, with good circulation, is used whether swung upward or downward.

There are patients who consult the proctologist for relief when it is not always possible for him to perform the type of operation which may seem to him as ideal as any at his disposal in the present state of our knowledge. I refer particularly to those patients who have such an inordinate prejudice against an abdominal colostomy that they refuse and refute any type of relief which involves the employment of this most valuable procedure.

In many instances one is forced to inform the person that there is nothing else to be offered. In a fairly large group of properly selected cases, however, a perineal colostomy will perform extremely satisfactory service and will be accepted by those patients whose lives would be otherwise sacrificed if they are given no alternative but the performance of an abdominal colostomy.

It is, therefore, interesting to note that there is a gradually increasing number of patients with perineal colostomies who have survived the five year limit without evidence of recurrence. For those persons who otherwise would have succumbed to the ravages of malignant conditions of the colon, several years at

Fig. 2.—Double barreled umbilical colostomy.

least of mental as well as physical comfort have been added to their lives.

With the proper instruction as to the care of the perineal colostomy, and regularity of diet and habit, these persons have been able to continue to pursue their occupations and, in many instances, have not been forced to change their mode of living.

The technic of perineal extirpation, as well as of abdominal extirpation, with the establishment of a perineal anus at the site of the colostomy, has progressed to a point at which it can be stated that practically as much involved glandular tissue can be removed by this method of procedure as by the type of operation known as the Miles technic.

As a matter of fact, one type of perineal extirpation, as suggested by Lynch, disposes of just as much of the rectum and its surrounding fat muscle and glands as does the perineal phase of the Miles operation.

In this type of excision, of course, there is no attempt made to conserve anything in the way of muscles, nerves or coccyx. The pelvic cavity, from the promontory of the sacrum down, is completely cleaned out. In this type of operation the stump of the sigmoid flexure, which would have been utilized in an abdominal colostomy, opens just below the pelvic floor. With a large rubber tube stitched into this stump and the cavity packed with gauze surrounding the tube, it is a perfectly safe procedure. As the wound heals and contracts, the sigmoidal stump gradually prolapses to the cutaneous level and forms the new artificial anus at the normal site.

Fig. 3.—Patient lying on left side. Perineal colostomy with slight mucosal prolapse closing stoma.

In some instances in which the growth is low in the anorectal canal and the sigmoid flexure is quite redundant with a long mesentery, the sigmoidal stump can be brought down to the perineal level and sutured at the time of operation.

In a growth requiring abdominoperineal extirpation, the technic of the abdominal portion of the operation

is the same as for the abdominal phase of the one stage Miles operation. Instead of severing the bowel and turning the sigmoidal stump up through the abdominal wall, the rectum and a portion of the sigmoid flexure, well above the growth, is pushed into the pelvic cavity and the new pelvic floor built from the lateral sheaths

Fig. 4.—Patient lying on left side. Stoma approximately one half size of normal anus.

of the mesentery of the sigmoid, just the same as with the Miles technic.

After closure has been effected, the perineal portion of the operation proceeds in the same manner excepting that the intact rectum and sigmoid flexure is brought down and out into the perineal wound and divided well above the tumor.

If sufficient healthy bowel with good circulation permits, the sigmoidal stump is sutured to the perineal skin; if not, the sigmoid flexure is sutured to the new pelvic peritoneal floor and severed well below it. The rubber tube is then inserted and stitched in place as previously mentioned, and dressings are applied exactly the same as if the entire operation had been performed from below.

While in the operation performed through the perineum it is not possible to ascertain the presence or absence of metastases to the liver, this is not a vital drawback; if metastases are present, nothing surgical can be done about them anyway.

CONCLUSION

In an experience of many years in which practically every type of single and multiple stage operation for the removal of a carcinoma has been performed, and while many types of colostomies have been established, the perineal stoma has retained a definite position in the list of operations at our disposal.

Every surgeon must recall some patients who absolutely refused an operation which included an abdominal colostomy. If those patients had been offered a perineal colostomy, after due explanation, I am convinced from my own experience that a fairly good proportion of those patients who died without operative relief would have had at least a longer life. Certainly they would have had more comfort, both physical and mental. Some reject operation and die because of their inordinate, and often unwarranted, fear of and their repugnance to abdominal colostomy.

7815 East Jefferson Avenue.

ABSTRACT OF DISCUSSION

DR. NEIL W. SWINTON, Boston: At the clinic our colostomies are routinely made on a level with the umbilicus at a point between the outer and middle thirds of the left rectus muscle. In our experience this type of colostomy has been very satisfactory. This allows a careful closure of the space between the colostomy and the parietal peritoneum on the left and prevents an occasional obstruction of the small bowel. In our early experience, when we did not do this, it resulted in two or three instances of herniation and obstruction of the small bowel. When discussing the question of colostomy, there is a point which one cannot overemphasize. With the completion of the operation for the removal of the disease and the formation of an artificial anus, the surgeon's obligation to that patient is far from finished. The greatest care and attention must be given to the future management of the colostomy and in teaching the patient to regulate his colostomy so that he will be able to return to his normal occupational and social status. We have found that a mildly constipating diet, the careful regulation of bowel function by irrigations every two to three days, which can be taken by the patients themselves, will in the vast majority of these cases return these people to a happy and useful existence.

DR. G. JOHNSON HAMILTON, New York: I am in agreement with Dr. Hirschman's predilection for the perineal stoma. I have been using it for years and believe that it functions at least as satisfactorily as an abdominal one and certainly is better psychologically. In a review of fifty-two Lynch operations I find that complications developed with the stoma in sixteen; in six of these a prolapse of the rectum developed which necessitated a cuff amputation, which was ordinarily performed in the office and without anesthetic. In ten of them a tendency toward constriction developed, five of them sufficiently severe to necessitate a plastic operation in the hospital. In none of them did the fibrosis extend more than 2.5 cm. from the skin edge. All these patients have now developed an individual technic which gives them adequate control and allows them to play their part in society without embarrassment. I have not tried the substitution of a colostomy for the umbilicus but agree with Dr. Hirschman that it seems a very good idea and certainly I will adopt it should I ever again have to make a permanent abdominal colostomy.

DR. CLEMENT L. MARTIN, Chicago: Dr. Hirschman's favorable experience with umbilical colostomy in a large number of cases makes him a rather strong advocate for it. There is a divergence of opinion here: he regards such a colostomy as less conspicuous and easier to care for—other men feel that a lateral colostomy has these advantages. I have been deterred from using it chiefly because of the possibility of obstruction. Midline colostomies are not very satisfactory except as temporary ones; if low there is commonly a mat of intra-abdominal adhesions about the bladder; if high and permanent there is, I think, more danger of obstruction. Three cases of obstruction following umbilical colostomy in the last few months have come to my attention: 1 while the patient was still in the hospital, 1 nine months, the other a little longer after operation. It is unfair to disparage umbilical colostomy on such evidence alone, but the danger of obstruction does compel consideration. As to a perineal stoma: Over a period of years it has been regarded as a poor, unsatisfactory site for a colostomy and it still is and the only excuse for it, as Dr. Hirschman has said, is when the patient refuses anything else. Perineal resection of the rectum without preliminary colostomy or laparotomy, at which time the presence of regional and liver metastases can be determined, is, in my opinion, rarely or never necessary.

DR. DESCUM C. MCKENNEY, Buffalo: I agree with the author, from a limited experience, that in most cases a perineal colostomy functions satisfactorily and, because it is in the location of the normal anus, the care of it is what the possessor has been accustomed to and hence he does not appreciate any very objectionable change. This colostomy is something to offer a patient when, in the rare case, he absolutely refuses an abdominal colostomy and then only if the location of the malig-

nant growth is suitable for the Lynch operation; i. e., it offers as good a chance for complete eradication as by any other method. Dr. Hirschman has long been an advocate of the umbilical colostomy and it has some distinct merits, especially when the transverse colon is utilized. When the mesentery of the pelvic colon is short a carefully plotted colostomy in the left lower quadrant to me is preferable. Utilization of the midline incision for a colostomy, below the umbilicus, shortens operating time and has many of the advantages claimed for the umbilical colostomy. The author is as careful about instructing his patients in the care of their colostomy as he is in the selection of the location for it. If this rule were followed by all surgeons there would be less objection to it. The layman, naturally, dreads the discomfort, leakage, odor, audible escape of gas, difficult care and unsightly appearance. I have my patients use an aluminum cap, which overcomes these objections and in addition offers support which tends to prevent hernia. Most surgeons who are doing many colostomies soon develop a method of their own, often improved by following practical suggestions from the patients themselves. Irrigating the colon daily or every second or third day, taking from thirty to forty-five minutes, often makes it possible for the patient to wear only a pad over the colostomy. Irrigation, however, as ordinarily carried out, is a messy, smelly operation, because there is no sphincter control; however, with an apparatus which supplies an artificial sphincter it is possible to empty the colon completely in a cleanly fashion. Such an apparatus I described and illustrated in a paper on Cancer of the Rectum, Pre-operative Treatment and Palliative Colostomy, read before the American Proctologic Society in May 1932.

DR. THOMAS E. JONES, Cleveland: With regard to the site of the colostomy, it should be put where it fits best. It so happens that, with the type of operation I do, it generally fits best in the midline incision about half way between the symphysis and the umbilicus. Of infinitely greater importance is the indication for colostomy. It is often indiscriminately done. My own feeling is that the obstruction is the only indication. Many will die from metastasis before they become obstructed with a cancer of the rectum, and in this group it is wrong to do a colostomy and bring disrepute to a good surgical procedure. Posterior resection will always have its adherents. A surgeon should do the type of operation with which he is more familiar, provided the factors of operability, mortality and curability compare favorably with other procedures in vogue. My own results are much better with the one stage abdominoperineal procedure.

DR. WILLIAM H. DANIEL, Los Angeles: Dr. Hirschman has presented an important subject and has covered it so thoroughly that I have little to add. He has advocated the umbilicus as the proper site for the permanent stoma and I have used it a few times and found it entirely satisfactory. It has been my custom to establish a permanent colostomy in the midline incision in performing the one stage abdominoperineal resection and in some cases of a permanent double barreled type. Since the care of a colostomy by the patient has become simplified by the use of irrigation and proper diet, cumbersome dressings are not necessary and most persons are able to disguise the location of the colostomy by proper adjustment of the clothing. The perineal stoma is being used by some men whenever possible and by others when the patient refuses the abdominal location. The mental factor is an important one in considering the future welfare of the patient. The abnormal openings which I have seen located in the perineum seemed to function to the satisfaction of the patients who had them.

DR. CLAUDE C. TUCKER, Wichita, Kan.: The colostomy question is a debatable one and will likely always be debatable. The condition calling for a colostomy depends on the choice of location. For a temporary colostomy, diverting the fecal flow, Dr. Hirschman has chosen one way, and the umbilicus is as good as any other unless the patient has a very short mesentery. Then I think it would be wise to choose another location. I

haven't heard Dr. Hirschman express himself on this. I have heard patients state that they would rather die than sacrifice their natural habits, and they did, and I have heard surgeons make the same remark. A colostomy, wherever located, is not so bad if properly taken care of and properly done, but to convince all patients of that is a different thing; therefore I heartily agree with Dr. Hirschman as to establishing a perineal colostomy; thus many lives would be saved which otherwise would be sacrificed. I have found the Lynch type of operation very satisfactory, establishing a perineal anus at the site of the colostomy, as Dr. Hirschman has stated. One can go as high up in the Lynch operation as one does in a Miles operation. Dr. Lynch has gone as far as 71 or 72 cm. and I have gone as high as 57.5 cm. The patient with a perineal colostomy has the urge to go to stool and he can sit on the stool and enjoy the newspaper. Some drive in a hundred miles without soiling themselves, and they are happy patients. In doing a resection we have to think of the natural contour of the body, especially with women, and we are more than justified in doing this type of colostomy.

DR. MONTAGUE S. WOLF, San Francisco: With all the talk about position of a colostomy and the way people are able to take care of colostomies, a colostomy is a terrible burden to put on a human being. It is certainly worse than an artificial limb; however, what we are after is life, and if we all want to have the longest life compatible with cancer of the rectum we must have first a wide excision of the cancer and then a colostomy. I think the Lynch operation does not get the main glands to the same extent as the abdominoperineal method of Miles. When one makes a perineal resection of this type one is likely to keep close to the bowel, and when one gets up far enough and is close to the bowel one cannot get the aortic glands of the mesentery. In other words the root of the mesentery is the part that must be removed: It is the part of the greatest consequence. The glands next to the colon have become infected through the former and it is no use removing these without having removed the glands infecting them.

DR. LOUIS J. HIRSCHMAN, Detroit: I stated that the best operation for the removal of carcinoma of the rectum and lower colon was a Miles one stage operation, and I tell my patients that. The best criterion of a good operation is one which will remove the entire lesion and all the involved glands so that one can still have a viable stump for the colostomy, whether it is placed high, low or sideways. The same stump of sigmoid which one swings upward for abdominal colostomy, whether an umbilical, lateral or inguinal colostomy, can be swung downward in most cases to the perineum. Before deciding on the type of operation, the surgeon should examine the patient carefully, instrumentally and radiologically. I mean by that that he should go to the x-ray department and should manipulate the barium filled sigmoid under the fluoroscope so as to know how much or how little sigmoid he has at his disposal and will not be embarrassed, after he has told the patient he will do a certain operation, to find he can't do it. This personal manipulation has been of invaluable use in my work, and I always feel that if a surgeon wants to fit his patient to the type of operation he had better stop operating. One must fit the operation to the case in hand. In the period of preparation, which lasts five to seven days, one cleans out the barium and otherwise prepares the patient. I mentioned perineal colostomy definitely to see if I could say a word which would help save the lives of those patients who absolutely refuse abdominal colostomy, and one has always had them. I do say that one can remove just as much tissue, just as many infected glands by an abdominoperineal operation with a perineal stoma in many cases as one can by an abdominoperineal operation with an abdominal stoma, and in a certain percentage of cases one can do a perineal operation of the Lynch type. I want to stress that a patient who would refuse an abdominoperineal operation with an abdominal stoma can be offered the same thing with a perineal stoma in about 7 to 10 per cent of the cases, and those who refuse the abdominal stoma would go off and die without relief otherwise, and one can give those few people the benefit of that type of operation when they refuse the other.

COMPRESSION OF BRACHIAL PLEXUS THE SCALENUS ANTICUS SYNDROME

FREDERICK LEET REICHERT, M.D.
SAN FRANCISCO

This report concerns the relief of symptoms by surgical means in 60 of 74 patients with compression of the brachial plexus (medial cord) due to displacement.

The symptoms of compression of the brachial plexus are the same as those produced by cervical ribs. This condition has been described in the past six years a number of authors. Some have used the term "neuritis of the brachial plexus, mechanical in origin" or "scalenus neurocirculatory compression" to indicate that the chief factor is pressure on the brachial plexus by the anterior scalenus muscle.

Fig. 1.—Relation of brachial plexus and the subclavian artery to the scalenus anticus and medius muscles and to the first rib. Small insert indicates the squeezing mechanism produced (1) by the two scalenus muscles (upper right) on the upper portion of the brachial plexus and (2) by the acute angle (upper left) produced by the lateral border of the scalenus anticus muscle and the first rib (after Theis¹).

Compression of the brachial plexus by a first dorsal rib was described over thirty years ago by Murphy.¹

Scant attention has been given in the literature to the nonoperative treatment of the symptoms produced by cervical ribs, by abnormal first dorsal ribs or by the squeezing mechanism of the scalenus muscles and the first rib, the so-called scalenus anticus syndrome. Surgical treatment has consisted in resection of the cervical rib, resection of a portion of the first rib and, finally, simple division of the anterior scalenus muscle.²

The condition was popularized by the report in 1935 of Ochsner, Gage and DeBakey,³ whose patients were cured by division of the anterior scalenus muscle.

From the Department of Surgery, Stanford University School of Medicine.

3. Ochsner, A.; Gage, M., and DeBakey, M.: Scalenus Anticus (Naffziger) Syndrome. *Am. J. Surg.* 28: 669 (June) 1935.

Theis,⁴ in 1939, found that, since the symptoms were aggravated by faulty posture, conservative treatment was all that was necessary for 17 of 20 patients with suspected compression. He corrected the posture, prevented fatigue and in some instances immobilized the arm and shoulder.

Stopford⁵ in 1919 reported on partial compression of the brachial plexus by a first dorsal rib and expressed the opinion that the essence of nonoperative treatment was to develop the trapezius muscle to such a point that it could support the pectoral girdle and so prevent the lower trunk of the plexus from being compressed by the rib. He advised faradic stimulation, exercises and massage to develop the trapezius muscle.

As early as 1907 Russel⁶ reported that a patient was able to control the pain through elevation of the shoulder, for example by putting the involved hand on the opposite shoulder. The patient was able to sleep when the arm was raised under the head, thus elevating the shoulder.

ETIOLOGY

Compression of the brachial plexus is a brachial neuritis, with or without vasomotor or vascular disturbances in the upper extremity, which appears in certain persons because of an abnormal development of the shoulder girdle (Todd⁷) or of the brachial plexus (Jones⁸), factors that permit friction or pressure on the brachial plexus and the subclavian artery. This friction or pressure, with the resultant irritation of some of the fibers that supply the scalenus muscles produces contractions and spasm of the scalenus anticus and scalenus medius muscles in particular, so that an abnormal elevation of the first rib occurs. This elevation in turn increases the angle between the lateral border of the scalenus anticus muscle and the first rib, squeezing the lower trunks of the brachial plexus and the subclavian artery and also squeezing the plexus between the posterior lateral border of the scalenus anticus muscle and the body of the scalenus medius muscle⁹ (fig. 1). Thus a vicious circle exists which is relieved when the anterior scalenus muscle is sectioned or when corrective posture is maintained day and night to overcome irritation of the plexus and spasm of the scalenus muscles. Trauma to the shoulder region or excessive strain on the shoulder and the supraclavicular region, such as that incurred by load carriers and soldiers,⁹ may be the exciting cause of symptoms.

SYMPTOMS AND SIGNS

Pain, tingling and numbness occur in practically all cases of compression of the brachial plexus. They may extend from the cervical, scapular or pectoral regions to the hand and fingers. Slight muscular weakness may be found, but atrophy and severe circulatory changes, such as cyanosis, coldness or gangrene of the fingers, are infrequent. The symptoms, therefore, are mainly sensory and sympathetic, with the pain of a dull, gnawing or burning character, and are affected by posture and work. Sleep is disturbed by the pain, and

sedatives give slight relief. The irritation may be limited to the upper portion of the brachial plexus, with pain and paresthesia radiating up the posterior part of the neck and the occipital region and downward over the shoulder to the scapular region. It may involve the pectoral region and the inner side of the arm and forearm, simulating anginal pain.¹⁰ Frequently the pain is limited to the distal half of an upper extremity, affecting the elbow, hand and middle fingers. Paresthesias and sensory disturbances may be bizarre in outline because of the involvement of sympathetic fibers.

DIAGNOSIS

The diagnosis of compression of the brachial plexus is made when local tenderness is found and the symptoms are reproduced by shifting the digital pressure vertically along the scalenus muscle over the width of the brachial plexus.

Pulling or pressing the affected shoulder downward, bending the head and neck to the opposite shoulder, turning the head to look over the affected or the opposite shoulder, pressing the affected arm against the chest with the shoulder depressed and throwing the shoulders and head back are other methods of aggravating the complaints and confirming the diagnosis.

Fig. 2.—Arrangement of three pillows to overcome the squeezing mechanism during sleep. The patient's head rests on pillow 3. When he is lying on his back, the shoulders rest on pillows 1 and 2. With the patient sleeping on one side, the shoulder rests on the mattress between pillows 1 and 2.

During examination relief of symptoms usually follows shrugging of the affected shoulder, shrugging the shoulders and bending the head and neck forward and bending the head and neck to the affected side.

TREATMENT

The accepted and satisfactory surgical treatment for compression of the brachial plexus which has not been relieved by conservative measures is the division of the scalenus anticus muscle close to its insertion onto the first rib. The technic of the operation is that described by Adson and Coffey,² modified by excision of a portion of the muscle as recommended by Ochsner, Gage and DeBakey.³

Section of this muscle was performed in 14 of 74 cases of compression of the brachial plexus prior to March 1941. Ten patients secured complete relief. One died from hemorrhage. In 1, subsequent injections of procaine hydrochloride into the operative area, with massage, finally abolished the remaining symptoms. Two patients were reoperated on, with relief. Both had the plexus freed from scar tissue, possibly from hemorrhage, and 1 also had a dorsal sympathectomy.

Conservative or nonoperative treatment was sufficient to bring relief of symptoms to 60 patients. The non-surgical management consists of variations of the following regimen, depending on the severity of the symptoms: (1) elevation of the shoulder by a sling or by holding the hand across the chest in a fold of the buttoned shirt or coat, (2) elimination of the type of work that aggravated the symptoms and (3) a change in sleeping habits. Since two thirds of the 74 patients complained that their symptoms were worse or at least severe during the night, patients were instructed to sleep on three pillows arranged as illustrated in figure 2. Most patients were accustomed to sleep either without a pillow or with one pillow, a few slept on their abdomens and only 2 had learned that sleeping with the affected arm over the head gave relief.

Experience had shown that relaxation of the scalenus muscles and obliteration of the squeezing mechanism was obtained by using three pillows so arranged that when the patient was lying on the back, the shoulders, head and neck were forced forward. When the patient lay on the side, with the shoulder on the mattress between the two under pillows (fig. 2 A, pillows 1 and 2), and the head on the third or top pillow (pillow 3), there was no sinking of the head toward the under shoulder. If the good shoulder was down, a fourth pillow, under the affected elbow and forearm, would help in keeping the affected shoulder elevated. If the patients were awakened by pain they invariably found either that they had slipped off the pillows or that the pillows had become disarranged. No sedatives were given, since too long an interval would elapse under sedation before the pain produced by the bad position on the pillows or by disarrangement of the pillows would finally awaken the patient. Although sleeping with the arms over the head relaxes the squeezing mechanism, it was found that this position was rarely maintained throughout the night.

COMMENT

Compression of the brachial plexus has been diagnosed in 74 patients. Of these, 42 were women, with the condition present on the right side in 16. Five showed on roentgenograms rudimentary cervical ribs bilaterally, and 3 had such ribs on the right side. Seven women had a scalenotomy, 2 were reoperated on and 1 of the 2 had a dorsal sympathectomy. Of 32 men with compression, 2 had it bilaterally and 10 had the right side involved. Three had rudimentary cervical ribs on both sides, 2 had such ribs on the right and 1 had them on the left side. Six men had scalenotomy, 2 for symptoms that simulated coronary disease. Later 1 of these had an alcoholic block of the thoracic sympathetic nerves for true angina and the patient finally died of coronary thrombosis.

Five patients, 3 men and 2 women, had pains simulating anginal attacks which could be produced by digital pressure over the scalenus anticus muscle, and 3 were relieved by the nonsurgical procedures.

Patients with symptoms of several months' duration were not completely relieved until after two, three or four weeks of conservative treatment.

SUMMARY

Symptoms of compression of the brachial plexus are similar to those of cervical ribs, namely pain, tingling and numbness in the upper extremity, the shoulder and the scapular, cervical and pectoral regions.

They are due to the squeezing mechanism which compresses the brachial plexus between the scalenus

anticus and scalenus medius muscles and the first rib. Spasm of these muscles elevates the first rib and establishes a vicious circle.

Treatment is surgical and nonsurgical.

Of 74 patients, 14 had scalenotomy, 10 achieving relief. The remaining 60 were relieved by conservative measures, consisting of rest and elevation of the shoulder on the affected side during the day and the use at night of three pillows so arranged for sleeping that the squeezing mechanism was overcome.

Clinical Notes, Suggestions and New Instruments

A SAFE METHOD OF APPLYING SOLIDIFIED CARBON DIOXIDE

C. C. CARPENTER, M.D., SUMMIT, N. J.

Unfortunately, the anatomic site of a cutaneous lesion must always be considered with the present methods of therapy with solidified carbon dioxide.

In the treatment of benign or malignant neoplasms of the skin and mucous membranes care must be taken that normal tissue is not frozen. With the older methods of cutting pencils from solid sticks, the very brittleness of the material caused it to chip. These small particles fell on nonpathogenic tissue, sometimes with serious consequences if the site of operation was around the eyes or within the body cavities. With the average duration of treatment of ten to thirty seconds the point on a solid stick is rapidly melted and a zone larger than the lesion is found to have been included in the treatment. Solidified carbon dioxide packed in metal tubes has the disadvantage of transmission of cold through the sides.

Fig 1—Treating angioma of upper eyelid with smallest applicator.

With the apparatus described here the plastic applicators insure complete insulation of the sides without danger to the operator's fingers or adjacent tissue (fig. 1). The amount of snow remaining in the applicator is at all times visible, and the finger tip plunger insures that no more than the required amount is at the tip, so that large surrounding normal areas are not frozen.

Several sized applicators insure the treatment of all such common lesions as verrucae, keratoses, angiomas, lymphangiomas, soft corns and nevi.

DESCRIPTION OF APPARATUS¹

Solidified carbon dioxide is formed by piercing a cartridge of carbon dioxide gas and allowing the gas to flow into a cone shaped expansion chamber (fig. 2). A patented tamping device, using the excess gas as a motivating force, tamps the snow as it is formed into a compact cone. The lower part of the machine may be unscrewed from the upper part, thus enabling the operator to release the cone of snow from its mold.

Fig. 2.—Machine for forming solidified carbon dioxide with plastic applicator.

A series of applicators with diameters varying in size from $\frac{5}{32}$ inch to $\frac{3}{4}$ inch is provided. The snow is forced into the applicators at the tip of the sleeve and is compressed into a hard pencil by means of a plunger or rammer. This is specially beveled so that the pencil formed will not drop out of the sleeve but must be pressed out gently. The operator is then able to regulate the speed of renewal of the snow at the active tip and adjust the pressure necessary for refrigeration.

The machine and the applicators are made of a light, strong and durable plastic. The nature of the material is such that it is also completely insulating and assures a 100 per cent efficiency and volume of snow obtained at the tip.

The snow machine, applicators and a box of twenty-four cartridges are contained in a kit $6\frac{1}{2}$ inches square, which may be put in a physician's bag and conveniently carried to any desired point. Refill cartridges in boxes of twenty-four are easily obtained when needed to replace those in the kit.

ACUTE APPENDICITIS WITH GENERALIZED PERITONITIS

TREATED BY INTRAVENOUS AND DIRECT INTRAPERITONEAL
INJECTION OF A SULFONAMIDE DERIVATIVE

JULIUS GOTTESMAN, M.D., AND HAROLD GOLDBERG, M.D., NEW YORK

The use of sulfonamide derivatives in the treatment of peritonitis of appendical origin was first reported in 1939 by Corry, Brewer and Nicol.¹ Further studies were made by Ravdin, Rhoads and Lockwood² and Michel.³ These authors, administering the drug intravenously, reported striking improvement in the mortality and morbidity of this disease in their series of cases. In 1941 Thompson, Brabson and Walker⁴ suggested

that the drug be introduced directly into the abdominal cavity at the time of operation. Rea⁵ concluded that the sulfonamides are most effective when introduced directly into the peritoneal cavity.

REPORT OF CASE

B. P., a Negro child aged $2\frac{1}{2}$ years, was admitted to the surgical service of Sydenham Hospital on July 25, 1941 with a four day history of vomiting, abdominal pains and constipation. Prior to hospitalization the child had been treated with cathartics and enemas.

On the first examination the patient did not appear to be acutely ill. The temperature was 102 F. The general physical examination was negative except for slight voluntary rigidity in both lower quadrants without any definite evidence of peritoneal irritation. The rectal examination was negative. The blood showed slight leukocytosis (13,400 cells). The urine was normal. No definite diagnosis could be established on admission.

During the first two days of hospitalization the temperature ranged between 99 and 102 F. On the fourth day following admission (eighth day of illness) vomiting recurred and the temperature rose to 102.6 F. The following day a sudden change for the worse occurred; the patient became listless and the vomiting fecal and projectile. The abdomen was distended and diffusely rigid and tender. The white cell count rose to 14,200 with 41 per cent band forms. A roentgenogram of the abdomen showed fluid levels of intestinal obstruction. A definite diagnosis of acute appendicitis with generalized peritonitis was now made, and because of the patient's poor condition and the duration of symptoms (nine days) conservative treatment was decided on. Continuous gastric suction through a Levin tube was begun and sodium sulfathiazole, saline and dextrose solution given intravenously.

The following day (tenth day of illness) a diagnostic abdominal puncture was made and a large amount of purulent fluid aspirated (250 cc.). Through the aspirating needle 5 Gm. of sulfapyridine in 100 cc. of distilled water was injected directly into the peritoneal cavity. The aspirated pus on culture was found to contain *Bacillus coli* and hemolytic streptococci. The intraperitoneal dose was repeated two days later. The child also continued to receive sodium sulfathiazole and saline and dextrose solution intravenously and also was given a transfusion of citrated whole blood on two occasions.

Two days after the second intraperitoneal injection a definite improvement in the child's general condition was obvious. The temperature fell to normal and the patient had spontaneous bowel movements. On the eighteenth day of illness the temperature rose again and the abdomen became distended. Examination at this time revealed a pelvic mass which could be palpated rectally. This pelvic abscess ruptured spontaneously through the rectum on the twenty-second day of illness, after which the child made an uneventful recovery and was discharged well.

The child was readmitted to the surgical service on October 15 with all the classic signs of acute appendicitis. A laparotomy was performed and an acutely inflamed appendix removed. The specimen showed evidence of previous rupture. Adhesions were found in the region of the cecum but elsewhere the abdomen was free of all signs of the previous attack of peritonitis.

SUMMARY AND CONCLUSIONS

In the case of acute appendicitis with generalized peritonitis here presented an operation in our opinion was contraindicated. The patient was treated by intravenous administration of sodium sulfathiazole, saline and dextrose solution, by transfusion of citrated whole blood and by the direct intraperitoneal injection of sulfapyridine. The child after the spontaneous evacuation of a pelvic abscess through the rectum recovered and was discharged cured. About two months later the child was readmitted with all the classic signs of acute appendicitis. An acutely inflamed appendix was removed which showed evidence of previous rupture. We are not aware of any reference in the literature to this method of administration.

5. Rea, C. E.: *Surg., Gynec. & Obst.* 73: 193 (Aug.) 1941.

We believe that the direct intraperitoneal method of sulfonamide medication could be of value in the treatment of various types of peritonitis, such as pneumococcic, gonococcic or streptococcic peritonitis, or in cases of postappendical peritonitis in which operation is contraindicated or deferred.

1185 Park Avenue—277 West End Avenue.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.
HOWARD A. CARTER, Secretary.

ACCEPTANCE OF ULTRAVIOLET LAMPS FOR DISINFECTING PURPOSES

After due consideration of the present status of the use of ultraviolet radiation as a germicide, in consultation with bacteriologists, physicists, chemists, ventilating engineers and other scientists, the Council on Physical Therapy has adopted the following regulations for acceptance of ultraviolet lamps for use as an adjuvant in the disinfection of air.

In this connection it is to be noted that a lamp used for germicidal purposes is a single unit in an installation, and that compliance of the ultraviolet output of a single lamp unit with the Council's requirements does not insure adequate radiant disinfection or the safety of the occupants of the room in which an installation of such lamps is in actual use. Obviously the manufacturer and distributor of such lamps must assume some responsibility for the adequacy of the lamp installation for purposes of radiant disinfection of the air and for the adequacy of the protection from injury of the occupants of the space irradiated. Concerning these questions the Council cannot undertake supervision or assume responsibility for the satisfactory performance of any particular installation.

Obviously in a school room occupied less than eight hours a day by teachers and pupils in apparently good health, the intensity of the ultraviolet irradiation at the level of the desks may be different from that required in a scarlet fever ward requiring continuous operation of the lamps to insure adequate disinfection. In both cases the total amount of direct and scattered ultraviolet radiation incident on the occupants must be kept below the level that will produce conjunctivitis, erythema and any other (at present unforeseen) injurious physiologic effects that may arise from prolonged irradiation. This requirement should be met by a suitable arrangement of the lamp fixtures and light baffles and not by requiring the pupil to wear glasses and a special covering of the parts of the body (face, hands) normally uncovered.

In this connection it is to be noted that the efficiency of the emission line 2,537A (angstroms) in producing an erythema is very high and, in contrast, the efficiency of this emission line in producing tan is very low. As a result of this slow acting protective mechanism (tanning skin pigmentation) the irradiated occupant of the room may suffer severe burns. The data governing the Council's Acceptance of Sun Lamps show that an intensity of 36 microwatts per square centimeter can produce an erythema in fifteen minutes. If the reciprocity law holds for very low intensities and long exposures, then the total intensity of the ultraviolet radiation (diffusely reflected from the walls and fixtures and emanating directly from the lamp) incident on the occupant for seven hours or less should not exceed five-tenths microwatt per square centimeter ($0.5\mu\text{W}/\text{cm}^2$) and for continuous exposure (twenty-four hours a day) should not exceed 0.1 microwatt per square centimeter of wavelength 2,537A. How to design the lamp installation to meet the requirements for adequate disinfection of a room and at the same time protect the occupants is a problem for solution by the sanitary engineer.

At the present juncture the design and installation of ultraviolet lamps in their fixtures for disinfecting purposes is empiri-

cal and the adequacy of disinfection by any given installation of lamps must be judged by clinical experience. For example, clinical evidence has been submitted to the Council showing that, in a scarlet fever ward (size about 60 by 27 by 11 feet) containing sixteen cubicles, four lamp units, each one emitting a radiant flux of 30 microwatts per square centimeter at 1 meter, were found inadequate; but eight lamp units in the ward, each unit protecting two cubicles, and a ninth unit at the entrance, prevented cross infection. This is a rather high intensity (requiring twenty minutes calculated time to produce a minimum perceptible erythema) incident on a person of average height, standing directly under a lamp fixture suspended from a ceiling of average height. A greater number of lamps, each one of lower ultraviolet intensity (say 20 microwatts per square centimeter at 1 meter) and lower power input, more evenly distributed throughout the room should be safer and equally efficient in disinfecting the air. This is a matter of engineering design, beyond the scope of the Council's purview.

PHYSICAL DATA ON GERMICIDAL LAMPS

Experimentally, applying equal amounts of energy of different wavelengths, it is found that the spectral band at 2,652A appears to produce the maximum bactericidal action and that the emission band at 2,537A is only about 70 per cent as effective. This difference in effectiveness is negligible in the present considerations because in readily obtainable sources of germicidal radiation, especially in the low vapor pressure (cold cathode) mercury discharge tube, which is well adapted for killing microorganisms, the ultraviolet radiant power of wavelength 2,652A is less than 0.2 per cent of that of wavelength 2,537A, the resonance emission band that dominates the whole ultraviolet spectrum of this type of lamp.

About 90 per cent or more of the total biologically effective ultraviolet radiation of wavelengths shorter than 3,132A emitted by the low pressure mercury discharge (whether in quartz or in a transparent glass tube) is concentrated in the emission line at 2,537A. For this reason the emission line at 2,537A, logically and by common consent, is taken as the standard of homogeneous ultraviolet radiation for evaluating the ultraviolet output of germicidal lamps, just as the wavelength 2,967A in the high vapor pressure (hot cathode) mercury arc is taken as the standard of homogeneous ultraviolet erythematogenic and antirachitic radiation in evaluating the ultraviolet output of therapeutic lamps.

The low pressure mercury discharge in a suitable glass tube or in a suitably filter jacketed quartz tube which readily transmits the strong, highly germicidal emission line at 2,537A but is opaque to wavelengths shorter than about 2,200A (that generate ozone) appears suitable to supplement other means of disinfection when operated under controlled conditions and limited to certain types of applications.

From the evidence available it appears that a minimum of 5,000 to 10,000 microwatt seconds per square centimeter ($\mu\text{W sec.}/\text{cm}^2$ or 50,000 to 100,000 ergs/ cm^2) of homogeneous radiation of wavelength 2,537A is required to produce adequate (practically 100 per cent) killing of microorganisms, especially bacteria. With an exposure of fifty to one hundred seconds this will require an intensity of 100 microwatts per square centimeter.

The Council has adopted 100 microwatts per square centimeter of homogeneous radiation of wavelength 2,537 angstroms as the unit of germicidal intensity (G. U.); that is, $1\text{ G. U.} = 100\mu\text{W}/\text{cm}^2$ of radiation of wavelength 2,537A.

Since the ultraviolet emission from the low vapor pressure mercury discharge tube is practically homogeneous radiation of wavelength 2,537A, such a lamp can be readily calibrated in absolute value and used as a standard. The intensity at 1 meter may be only one fifth of the Council's unit, or 20 microwatts per square centimeter, for safety to the occupants. This will require a minimum exposure of two hundred and fifty to five hundred seconds for adequate disinfection, which will depend on the rate of circulation and average distance of the air in front of the lamp. Evidence has been submitted to the Council

showing that cross infection in a contagious ward may be prevented by using a sufficient number of lamp units, each unit having an intensity of 30 microwatts per square centimeter at a distance of 1 meter from the burner. This will require an exposure of one hundred and sixty-seven to three hundred and thirty-four seconds for adequate disinfection, which implies a slow movement of the air in front of the lamp installation.

SCOPE OF THE COUNCIL'S ACCEPTANCE OF ULTRAVIOLET LAMPS FOR DISINFECTING PURPOSES

The Council has given careful consideration to the feeling, expressed by manufacturers vitally concerned in the matter, that the general acceptance of the use of ultraviolet radiation as a sanitary agent may necessitate some form of regulation, and that ultraviolet generating units offered to the public and medical profession may be classed with antiseptic agents requiring a degree of control of their potency and keeping qualities.

Under this caption is given an analysis of various proposed applications of ultraviolet radiation as a disinfectant and a statement of the specific applications that appear to fall within the Council's purview.

The advantages and disadvantages of the use of germicidal ultraviolet radiation for sterilizing purposes are summarized in the recent (1941) issue of "The Chemical Action of Ultraviolet Rays," by Ellis and Wells, second edition, by Francis F. Heyroth (see p. 718, "The Sterilization of Water"). L. R. Koller (*J. Applied Physics* 10:629, 1939) found that while sterilization of glassware and dishes is possible by means of ultraviolet radiation it was very important to start with fairly clean surfaces. Practically the same results are reported in a recent investigation by J. W. Appling and F. W. Tanner on the "Bactericidal Effect of Ultraviolet Rays on Micro-Organisms on Restaurant Glassware" (*Proc. Soc. Exper. Biol. & Med.* 47:51, 1941). While they noted decided improvement on irradiation, complete sterilization did not result in every case. In this connection reference is made to an editorial on "Disinfection by Light" (*Brit. M. J.* 2:707 [Nov. 23] 1940) showing that much remains to be done in studying the capacity of such lamps to reduce the dangerous bacterial content of air, not only under controlled laboratory conditions, but also in the more difficult and varied circumstances of practical use.

In this connection it is important to note that in order to kill a micro-organism a direct hit by ultraviolet rays of sufficient intensity is required. This is difficult to accomplish on the edge of a drinking cup, also in a liquid containing suspended matter or in air laden with dust particles that shield the organism. As an effective germicide a product must effect practically 100 per cent killing. Ultraviolet germicidal rays cannot penetrate deeply and hence may be absorbed by finger marks or other contamination on a drinking cup. The ultraviolet germicidal lamp, therefore, appears to be an uncertain means of sterilizing solid objects (drinking cups, combs, brushes, shaving utensils, shoes, toilet seats) even if irradiation of the whole surface is possible.

At this time satisfactory evidence is not available to warrant acceptance of ultraviolet lamps by the Council for disinfecting solids. Furthermore, the Council is not fully convinced at the present time that it should assume the responsibility in this matter. The whole subject is too new, too complex and apparently too uncertain where virulent organisms (e. g., typhoid) may be concerned in spreading epidemics.

Some evidence seems to indicate that the ultraviolet germicidal lamp can be used for sterilizing water, beverages and the like but only after adequate removal of suspended material; and it is applicable only to liquids which are highly transparent to ultraviolet germicidal radiation.

In a few cases in which chemical methods of sterilization of water may be harmful, as for example for surgical purposes (mentioned by Ellis and Wells), under certain conditions irradiation with ultraviolet lamps is reported to be useful. This acceptance is not concerned with such applications, which do not appear to be very wide. Moreover, it is not clear wherein

sterilization by ultraviolet rays is superior to boiling or distillation of the water used.

The use of ultraviolet radiation for disinfecting air in industrial plants, barracks, school rooms, assembly halls, refrigerators and so on also appears to be outside the Council's purview. In fact, at this juncture the whole question of the use of ultraviolet radiation for disinfecting purposes is too complex and too little understood for the Council to do more than attempt to keep the medical profession informed regarding particular ultraviolet lamps that are acceptable for use in this method of disinfecting air in hospitals, nurseries and operating rooms (relatively free from dust) as practiced by present day empirical methods.

TENTATIVE REQUIREMENTS FOR ACCEPTANCE OF ULTRAVIOLET LAMPS FOR DISINFECTING AIR

Clinical evidence submitted to the Council shows that under properly controlled conditions killing of air borne micro-organisms by ultraviolet rays may be used to supplement other methods of disinfecting air for prevention of cross infection in contagious wards in nurseries and hospitals, and for reducing air borne infection of wounds in operating rooms.

In considering ultraviolet generators for disinfecting purposes the Council makes no distinction between lamps for use in air conditioning ducts and lamps for use in open rooms in which there is only a slow circulation of air. In both cases a sufficient number of lamps must be provided to insure adequate disinfection of the air as determined by approved culture tests or other accepted procedures.

To comply with the Council's requirements the ultraviolet spectral energy distribution of the germicidal lamp shall be comparable in lethal effectiveness with the low vapor pressure mercury discharge tube, in which the dominant radiation is of wavelength 2,537Å.

The minimum intensity at right angles to and at a distance of 1 meter from the plane of the lamp tube in its fixture shall not be less than the germicidal equivalent of 20 microwatts per square centimeter of homogeneous radiation of wavelength 2,537Å. The useful life of the lamp shall not be less than four thousand hours. During this period the ultraviolet output shall not fall below the herein specified minimum intensity. To meet this requirement the lamp may be provided with a voltage regulator to compensate for the decrease in intensity of ultraviolet with usage; or the lamp may emit a sufficient excess of ultraviolet radiation when new, so that the output shall not fall below the specified minimum value ($20 \mu\text{W}/\text{cm}^2$ at 1 m.) in less than four thousand hours' operation. In either case the installation shall be provided with adequate safeguards against overexposure of the occupants of the room to ultraviolet radiation. The burner of the lamp shall be of glass or of suitably filter jacketed quartz, highly transparent to the emission line at 2,537Å, and opaque to radiation of wavelengths shorter than 2,200Å, to prevent the generation of the injurious amount of ozone, largely produced by these short wavelengths. To insure compliance with these requirements the lamp may consist of one, two or three tubes, mounted and operated as a unit.

For consideration of acceptance by the Council, the manufacturer shall submit a lamp unit in its fixture, permanently marked as to its useful life, and its radiant flux in microwatts per square centimeter of wavelength 2,537Å, at 1 meter under the normal power input used to insure a useful life of four thousand hours or more. In addition the manufacturer shall submit satisfactory clinical evidence, obtained over a period of not less than four winter months, of the effectiveness of an installation of such lamps in maintaining sterilized conditions in the space (hospital, nursery) subjected to radiant disinfection. For statistical purposes in improving installations, included in this evidence (for the present at least) is to be a statement of (1) the size of the room and the average number of occupants (and their ailments), (2) the number and arrangement of the lamp units, (3) kind and amount of ventilation and (4) the procedure to determine and maintain the intensity above the minimum level during the useful life of the lamp.

PROCUREMENT AND ASSIGNMENT SERVICE MAKES RECOMMENDATIONS TO ALL PHYSICIANS

Under the heading Medical Preparedness in this issue of THE JOURNAL is an official statement from the board of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians. Here are recommendations to all physicians with reference to the places they may occupy in the national emergency. There are directions addressed specifically to (1) medical students, (2) recent graduates, (3) interns who have completed twelve months in a hospital, (4) members of staffs of hospitals, (5) all physicians under 45 years of age and (6) all physicians over 45 years of age.

These recommendations, it will be observed, do not state specifically that any group, either medical students, interns or physicians, will be deferred by draft boards. Congress did not provide for blanket deferment of any group. However, authorities in the Selective Service have indicated their desire to cooperate with the Procurement and Assignment Service; any bona fide medical student in good standing or any physician called by the draft board may file an appeal.

The offices of the surgeon generals of the Army and of the Navy have arranged to permit junior and senior students who have enrolled in the medical administrative corps in the Army or who have obtained ensign commissions in the United States Naval Reserve to complete their medical education. Obviously the Procurement and Assignment Service must depend on the assurances of the Selective Service System and of the Army and Navy for proper action in these matters.

Apparently some physicians, perhaps even many, have been confused by the publication of the enrolment blank which appeared in previous issues of THE JOURNAL of THE AMERICAN MEDICAL ASSOCIATION and in the state journals and by subsequent changes in procedure. Let us bear in mind that conditions change from week to week, almost from day to day. A procedure is initiated to obtain a certain effect and to supply a certain need. When the effect is obtained and the need is satisfied, that procedure becomes obsolete. The blanks which were published in THE JOURNAL served to bring in enough applications to meet the immediate needs of the Army and Navy Medical Corps. Every one of the men under 36 years of age who filled out that blank has been considered to be a volunteer available for immediate service. Nevertheless, all names are being checked with the roster at the headquarters office of the American Medical Association. Those who are especially qualified in certain specialties are being given special consideration for the kind of work for which they are particularly fitted.

Apparently a number of physicians, even some of advanced age, felt that in filling out these blanks they were making themselves available for immediate service with the Army or Navy or in some civilian capacity. Some are resentful that they have not been called; others are fearful that they may be called. Hence it is recommended that every physician, whether or not he has filled out any enrolment blank previously, should read most carefully the announcements which appear in this issue and which are specifically directed to physicians of definite age groups. Within the near future an enrolment blank will again be sent to every physician in the United States under the auspices of the Procurement and Assignment Service. This will give opportunity for every physician in the United States to enroll himself with that service as ready to serve a specific need for which he is fitted. The Procurement and Assignment Service proposes also to make available to every physician who does enroll a certificate and a numbered button which will indicate to every one that he is a man who has offered to do his utmost for our government in its time of emergency.

Also under preparation is a statement consisting of questions and answers which have come from many physicians in many parts of the country. This statement will be published in THE JOURNAL just as soon as it is available, and reprints will be made available for those who wish to secure them.

SYNERGIC TOXINS OF DIPHTHERIA
GRAVIS

Striking indeed is the contrast between the optimism that prevailed during the first three decades of the twentieth century with regard to the successful serologic mastery of diphtheria and the pessimism and perplexity that characterize the present decade. The first indication of this growing pessimism dates from 1927, when Deicher and Agulnik¹ recorded a steady rise in diphtheria mortality in the Virchow Krankenhaus, Berlin, the 5 per cent mortality of 1924 having increased to 26.7 per cent. Within two years similar epidemics of clinically refractory cases were reported from Czechoslovakia, France, Italy and Rumania, with later spread to the British Isles.²

The newly recognized malignant diphtheria is characterized by hypertoxicity. There is relatively little membrane formation in the throat but severe local edema and necrosis, "bullneck," albuminuria, subcutaneous and submucous hemorrhages, and neurologic complications. The bullneck is due to massive cellulitis, with only minor enlargements of the cervical lymph nodes. Among the necropsy appearances are renal, cardiac, adrenal and neurologic degenerations, with occasional focal necroses in the spleen. Therapeutically the hypertoxic cases are almost totally refractory to diphtheria antitoxin, twenty to one hundred times the usual therapeutic dose having been injected intravenously without demonstrable curative effects. Moreover, diphtheria gravis is apparently not prevented by artificial immunization with any of the prophylactic agents in current use.

Following recognition of this refractory type of diphtheria a voluminous European literature was developed, but without a definite lead to research till the disease reached its peak in the British Isles. In the course of routine laboratory examinations, Anderson and his colleagues³ of the University of Leeds then gained the impression that a new and relatively stable type of the diphtheria bacillus was involved. The culture medium giving the sharpest differentiation is heated blood agar ("chocolate") containing 0.04 per cent of potassium tellurite. It is essential that the meat extract used in the preparation of this tellurite chocolate medium should not be heated above 75 C. but sterilized by filtration.

The characteristic diphtheria gravis or "Michaelma's daisy" colony on this medium is dark gray or gray black with distinctive petal-like radiations about a deeply stained center. No other bacterium thus far studied by Anderson and his co-workers produces a colony at all closely resembling this. For all strains of the diphtheria bacillus exhibiting this colony structure, Anderson suggests the name *B. diphtheriae gravis*, with

B. diphtheriae mitis reserved for the conventional diphtheria colony. Under this nomenclature the Park-Williams strain 8 would be classified as *B. diphtheriae intermedius*, the strain being half way between *mitis* and *gravis*.

Clinical applications of this new classification were afterward made by the Zinnemanns,⁴ who examined 1,300 clinical cases during the 1936 Ukrainian epidemic. They found that 96 per cent of all cultures recovered during life from all fatal cases in this epidemic were of the *gravis* type. The usual commercial diphtheria antitoxin would protect guinea pigs equally well against this toxin, and a special antitoxin prepared by immunizing animals against *gravis* filtrates was not found superior to the ordinary commercial product.

From these results it became evident that there is something radically wrong in conventional theory or technic. One conceivable error arises from the routine method of producing diphtheria toxin. In this technic the organism is grown for a long time in a fluid medium in such a way as to favor oxidation for the production of growth energy. In the infected throat, in contrast, the bacillus is grown on a solid medium and presumably uses tissue carbohydrates as its source of energy. To imitate the natural method of toxin production, O'Meara⁵ grew *gravis* strains for forty-eight hours on Loeffler's blood serum. The micro-organisms were then suspended in saline solution and allowed to stand about twenty-four hours. The resulting saline extract (or autolysate) was then freed from organisms by centrifugation followed by Berkefeld filtration.

Inoculated subcutaneously in 1 to 2 cc. doses, such extracts never cause more than a slight local temporary edema in guinea pigs. In 5 cc. doses, however, the extracts occasionally cause death, with the usual post-mortem appearances of death from diphtheria toxin. When the *gravis* extract is inoculated in 0.2 cc. doses intracutaneously, however, it is found to have distinctive properties. This is shown by immediate wheal production, usually reaching about an inch in diameter by the end of thirty minutes. Within two hours a red flush originating at the center has usually spread outward to cover the entire swelling.

If the saline extract is centrifuged but not filtered, so as to contain a certain amount of bacterial detritus, an even more pronounced intradermal reaction is noted. Within two or three days a central area of necrosis half an inch in diameter may be formed. In control tests with *mitis* or *intermedius* strains, little or no immediate cutaneous reaction is noted and the inclusion of unfiltered detritus does not enhance the intracutaneous toxicity. From this and other evidence O'Meara concludes that *gravis* strains grown on a solid medium form little or no routine diphtheria toxin but do form a product having properties analogous to those of the

Duran-Reynals⁶ "spreading factor" formed from invasive strains of staphylococcus or streptococcus.

The O'Meara synergic theory, however, was deduced from subcutaneous tests in which gravis extract was added to routine diphtheria toxin. Injected subcutaneously at the central part of the guinea pig abdomen, the mixture causes an enormous edematous swelling, often extending from the neck to the pubis. A large necrotic slough eventually forms. When the dose is sufficiently large to cause death, the time of death is determined by the routine toxin dose and is in no way related to the amount of gravis extract. Necropsy appearances usually include edema of the lungs, pleural effusion and pale adrenal glands, with an occasional hemorrhage in the spleen.

From such evidence O'Meara concludes that neither the routine diphtheria toxin nor the saline extract alone is able to produce the classic picture of diphtheria gravis but that the two products acting together are able to do so. He refers to these two synergic toxins as substance A and substance B. Toxin A is presumably identical with the routine mitis exotoxin, while B occurs in highest concentration as gravis endotoxin. These two substances acting together constitute fully potentiated diphtheria toxin. Two antibodies, anti A and anti B, are presumably necessary to overcome this synergic effect.

O'Meara finds this theory a logical explanation for the curious anomalies in toxin-antitoxin titration, such as the "Ehrlich phenomenon," the "Danysz phenomenon" and other nonagreements with the laws of multiple proportion. Proof that B. diphtheriae mitis produces a toxin consisting almost solely in A substance offers a logical explanation for the therapeutic efficiency of diphtheria antitoxin in the treatment of milder clinical cases. According to O'Meara's experimental data commercial antisera consist almost exclusively of anti A toxin, the anti B component conceivably being lost during the process of manufacture. Proof that B. diphtheriae gravis forms a superabundance of B toxin, which acts as a vector for a Duran-Reynals spreading factor, offers a logical explanation from the clinical failure of routine antitoxin serum in the treatment of malignant cases. Broader implications of O'Meara's theory arise from the fact that failures to obey the law of multiple proportions are not restricted to diphtheria toxin-antitoxin reactions but have also been described for other bacterial toxins.

According to a war censor release,⁷ diphtheria gravis was introduced into Halifax, Nova Scotia, recently but has been checked and its local recurrence made unlikely by vigorous cooperation between the local health authorities and an expedition of eleven experts sent from the Harvard Medical School. Sulfadiazine plus routine antiserum were used in fighting this epidemic. Sulfadiazine was administered to all carriers.

VITAMINS FOR GRAY HAIR

"My hair is gray but not with years, nor turned it white in a single night." Thus spoke the poet. The phenomenon of sudden or rapid graying of the hair under the stress of fear, anxiety or other deeply disturbing nervous effects is well known. The gradual graying of the hair is also interesting. Many a worker finds difficulty in securing employment because of premature grayness of the hair. The whole process has been a mystery to medical science for many years.

An interesting account by Aleš Hrdlička in his book "The Old Americans" discusses the case of Major A. W. Greely, arctic explorer, who in 1884, toward the end of an exceedingly difficult trip of arctic exploration, had his hair turn completely white. On his return to civilization the whiteness began to disappear gradually and to return to a nearly normal condition. Writing in 1922, General Greely said "When rescued at Cape Sabine in 1884 my hair was entirely white, due probably to the continuous condition of semistarvation from which I suffered for over nine months. Within a year my hair darkened considerably, though it never returned entirely to its original coloring."

This item, written more than fifteen years ago, is strangely apropos in these days when attention is being turned more and more to the relationship of the diet to the graying of hair.

Recent reports in newspapers and magazines assert that the color of the hair can be restored by the administration of vitamins. Most of these reports have centered around the supposed virtues of para-aminobenzoic acid, said to be especially effective in restoring color to the gray hair of persons whose hair has been red. Para-aminobenzoic acid has been isolated from yeast, definitely identified, and is considered to be the substance in yeast extracts which reverses the bacteriostatic effect of sulfanilamide. In the laboratory it has been shown to be a bacterial growth factor. Ansbacher has claimed that it is a growth promoting factor for the chick and a factor which is curative of gray hair which develops in black rats when maintained on certain types of synthetic diets. Sieve¹ has fed doses of 100 mg. twice daily to adults and has reported that after about two months there was darkening of the hair in all instances. Confirmatory reports by qualified investigators have not yet appeared. Because of the publicity that has been given to the work, many patients have been led to request treatment by their physicians.

A diversity of opinion still prevails about the relation between diet and graying of hair in animals. Most investigators have been unable to verify Ansbacher's observation that para-aminobenzoic acid is related in any way with the phenomenon of graying of hair in animals. The recent report of Unna, Richards and

1. Sieve, B. F.: Science 91:257 (Sept. 12) 1941.

Sampson² of the Merck Institute states that black rats which are fed a synthetic diet deficient in pantothenic acid become gray in about four to six weeks. Pantothenic acid at a level of 100 micrograms a day will prevent or cure this condition. Para-aminobenzoic acid in these experiments was entirely ineffective.

Elvehjem and his collaborators³ substantiated this work in its entirety. Williams⁴ found that pantothenic acid was without effect on the graying of hair. György and Poling⁵ believe that both pantothenic acid and biotin, another less well known member of the vitamin B complex, are necessary to prevent or cure nutritional achromachia—loss of hair color—in animals. Their lack of success has been attributed to the fact that the supplementary feeding of pantothenic acid used was too small.

Over ten years ago it was observed by a number of biochemists interested in nutritional anemia that black haired rats became gray on a milk diet. When the anemia was developed on this diet it was cured by administration of iron and copper and the color of the hair likewise was restored to normal. Agnes Fay Morgan⁶ and others showed in 1938 that a similar condition of gray hair could be produced in animals by a diet that did not contain all factors of the vitamin B complex. Thus came the conviction that vitamins may be concerned with this phenomenon. Even yet the experimental evidence is conflicting.

Is para-aminobenzoic acid really concerned with the maintenance of normal dark hair color in man? If gray hair is darkened by administration of relatively large amounts of this substance, the effect may be due simply to the excretion into the hair of some paraphenylenediamine-like compound which acts like a dye. Not all people whose hair has turned gray are necessarily suffering from a demonstrable vitamin deficiency. Before further experimental work is done on human beings it would be well to exhaust the possibilities of animal experimentation to ascertain the metabolic function of these substances that are present in yeast. Further, in view of the paucity of information about the functions of para-aminobenzoic acid, it would be highly desirable to know something about the metabolic history of this chemical in the body before relatively large doses are administered to patients over comparatively long periods of time. Finally, the evidence in behalf of some definite relationship between intake of vitamins and graying of hair is far more convincing for pantothenic acid than for para-aminobenzoic acid.

Current Comment

FACILITIES FOR SELECTIVE SERVICE REGISTRATION AT ANNUAL CON- GRESS ON MEDICAL EDUCA- TION AND LICENSURE

Elsewhere in this issue appears the program of the Congress on Medical Education and Licensure to be held February 16-17 in Chicago. Special emphasis is placed in this year's program on medical preparedness as it affects the training of physicians. The acceleration of the medical curriculum will be a major topic of discussion. Physicians or others living outside of Chicago who attend and who are required to register under the Selective Service regulations on February 16 can do so between 7 a. m. and 9 p. m. at the congress in the Palmer House. All citizens between the ages of 20 and 44 inclusive who were not registered on Oct. 16, 1940 or on July 1, 1941 are required to register.

THERAPEUTIC RESEARCH CORPORATION OF GREAT BRITAIN LIMITED

The formation of the Therapeutic Research Corporation of Great Britain Limited has been announced by five leading British pharmaceutical manufacturers. The principal objects of the T. R. C., as it is to be known, are:

To provide for the coordination and extension of research in matters of common interest with a view to accelerating the discovery of new substances for the service of therapeutic and preventive medicine, to ensure proper collaboration with medical, dental and veterinary practitioners in the introduction of new medicinal substances and to assist in the advancement of the art of medicine by the subsidization of research on a broader and more rational basis than has so far been possible in the British pharmaceutical industry.

To provide for the pooling of manufacturing facilities, where desirable.

To enable the industry to cooperate more effectively in national planning by presenting to the government through its appropriate medical, dental, veterinary, scientific and technical organizations the pooled knowledge and facilities acquired by the constituent companies in the field of therapeutic research.

Products evolved as a result of research sponsored by the corporation will be marketed and sold by the constituent companies under a common name. The T. R. C. will assist wherever practicable in simplifying the nomenclature of new medicinal substances. The announcement is significant, since it points the way to a desirable trend in drug research and marketing. Apparently the pooling of research interests involved in the formation of the organization is not intended to be merely a wartime expedient. While a similar idea had been frequently advocated in this country,¹ the first step in this direction has been taken in Great Britain. The functioning of the T. R. C. and its influence on drug research will no doubt influence greatly the attitudes of both the medical profession and the drug manufacturers of America.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

RECOMMENDATIONS TO ALL PHYSICIANS WITH REFERENCE TO THE NATIONAL EMERGENCY

All inquiries concerning the Procurement and Assignment Service should be sent to the Executive Officer, 5654 Social Security Building, Fourth and Independence avenues S.W., Washington, D. C., and not to individual members of the Directing Board or of committees thereof.

I. MEDICAL STUDENTS

A. All students holding letters of acceptance from deans for admission to medical colleges and freshmen and sophomores of good academic standing in medical colleges should present letters or have letters presented for them by their deans to their local boards of the Selective Service System. This step is necessary in order to be considered for deferment in class II-A as a medical student. If local boards classify such students in class I-A, they should immediately notify their deans and if necessary exercise their rights of appeal to the board of appeals. If, after exhausting such rights of appeal, further consideration is necessary, request for further appeal may be made to the state director and if necessary to the national director of the Selective Service System. These officers have the power to take appeals to the President.

B. Those junior and senior students who are disqualified physically for commissions are to be recommended for deferment to local boards by their deans. These students should enroll with the Procurement and Assignment Service for other assignment.

C. All junior and senior students in good standing in medical schools who have not done so should apply immediately for commission in the Army or the Navy. This commission is in the grade of Second Lieutenant, Medical Administrative Corps of the Army of the United States, or Ensign H. V. (P.) of the United States Navy

Reserve, the choice as to Army or Navy being entirely voluntary. Applications for commission in the Army should be made to the corps area surgeon of the corps area in which the applicant resides, and applications for commission in the Navy should be made to the commandant of the naval district in which the applicant resides. Medical R. O. T. C. students should continue as before with a view of obtaining commissions as First Lieutenants, Medical Corps, on graduation. Students who hold commissions, while the commissions are in force, come under the jurisdiction of the Army and Navy authorities and are not subject to induction under the Selective Service Act. The Army and Navy authorities will defer calling these officers to active duty until they have completed their medical education and at least twelve months of internship.

II. RECENT GRADUATES

On successful completion of the medical college course, every individual holding commission as a Second Lieutenant, Medical Administrative Corps, Army of the United States, should make immediate application to the Adjutant General, United States Army, Washington, D. C., for appointment as First Lieutenant, Medical Corps, Army of the United States. Every individual holding commission as Ensign H. V. (P.), U. S. Navy Reserve, should make immediate application to the commandant

of his naval district for commission as Lieutenant (J. G.) Medical Corps Reserve, U. S. Navy. If appointment is desired in the grade of Lieutenant (J. G.) in the regular Medical Corps of the U. S. Navy, application should be made to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

III. TWELVE MONTHS' INTERNS

All interns should apply for a commission as First Lieutenant, Medical Corps, Army of the United States, or as a Lieutenant (J. G.), United States Navy or Navy Reserve. On completion of twelve months' internship, except in rare instances in which the necessity of continuation as a member of the staff or as a resident can be defended by the institution, all who are physically fit may be required to enter military service. Those commissioned may then expect to enter military service in their professional capacity as medical officers; those who failed to apply for commission are liable for military service under the Selective Service acts.

IV. HOSPITAL STAFF MEMBERS

Interns with more than twelve months of internship, assistant residents, fellows, residents, junior staff members and staff members under the age of 45 fall within the provisions of the Selective Service acts, which provide that all men between the ages of 20 and 45 are liable for military service. All such men holding Army commissions are subject to call at any time and only temporary deferment is possible, on approval of the application made by the institution to the Adjutant General of the United States Army certifying that the individual is temporarily indispensable. All such men holding Naval Reserve commissions are subject to call at any time at the discretion of the Secretary of the Navy. Temporary deferments may be granted only on approval of applications made to the Surgeon General of the Navy.

All men in this category who do not hold commissions should enroll with the Procurement and Assignment Service. The Procurement and Assignment Service under the executive order of the President is charged with the proper distribution of medical personnel for military, governmental, industrial and civil agencies of the entire country. All those so enrolled whose services have not been established as essential

in their present capacities will be certified as available to the Army, Navy, governmental, industrial or civil agencies requiring their services for the duration of the war.

V. ALL PHYSICIANS UNDER FORTY-FIVE

All male physicians under 45 are liable for military service, and those who do not hold commissions are subject to induction under the Selective Service acts. In order that their service may be utilized in a professional capacity as medical officers, they should be made available for service when needed. Wherever possible, their present positions in civil life should be filled or provisions made for filling their positions, by those who are (a) over 45, (b) physicians under 45 who are physically disqualified for military service, (c) women physicians and (d) instructors and those engaged in research who do not possess an M.D. degree but whose utilization would make available a physician for military service.

Every physician in this age group will be asked to enroll at an early date with the Procurement and Assignment Service. He will be certified for a position commensurate with his professional training and experience as requisitions are placed with the Procurement and Assignment Service by military, governmental, industrial or civil agencies requiring the assistance of those who must be dislocated for the duration of the national emergency.

VI. ALL PHYSICIANS OVER FORTY-FIVE

All physicians over 45 will be asked to enroll with the Procurement and Assignment Service at an early date. Those who are essential in their present capacities will be retained and those who are available for assignment to military, governmental, industrial or civil agencies may be asked by the Procurement and Assignment Service to serve those agencies.

The maximal age for original appointment in the Army of the United States is 55. The maximal age for original appointment in the Naval Reserve is 50 years of age.

FRANK H. LAHEY, M.D., Chairman.

HARVEY B. STONE, M.D.

JAMES E. PAULLIN, M.D.

HAROLD S. DIEHL, M.D.

C. WILLARD CAMALIER, D.D.S.

SAM F. SEELEY, M.D., Executive Officer.

PROTECTION OF CIVIL RIGHTS OF PERSONS IN MILITARY SERVICE

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION

Designed to protect from impairment the civil rights of all members of the Army, Navy, Marine Corps, Coast Guard and all members of the United States Public Health Service detailed by proper authority for duty with the Army or Navy, a law was approved by the President, Oct. 17, 1940, commonly referred to as the Soldiers' and Sailors' Civil Relief Act of 1940. In substance, this law is an up-to-date revision of a similar enactment passed during the first world war, and its fundamental purpose is to free persons in the military service from harassment and injury to their civil rights during their term of military service and thus to enable them to devote their entire energy to the defense needs of the nation.

The provisions of the law, broadly stated, apply to persons on active duty with any branch of the services mentioned and to those in training or undergoing education under the supervision of the United States preliminary to induction into the military services who (1) may become defendants in a court action, (2) have dependents occupying a dwelling for which the agreed rent does not exceed \$80 a month, (3) may have contracted, prior to entry into service, for the purchase of real or personal property on the instalment plan, (4) may have obligations relative to mortgages on real or personal property, (5) may hold policies of life insurance of a face value not in excess of \$5,000, (6) may have taxes or assessments on real property falling due, (7) may have initiated or acquired a right to lands owned or controlled by the United States or (8) may become liable for income taxes. Generally the law provides remedies in the form of suspension of proceedings and transactions during the time a person is in the military service only when, in the opinion of the court, such person's opportunity and capacity to perform his civil obligations are impaired by reason of his being in military service.

GENERAL RELIEF

Before any judgment in default may be entered in any court, the plaintiff must file an affidavit showing either that the defendant is not in military service, that he is in such service or that the plaintiff is unable to determine whether or not the defendant is in service, as the case may be. If the absent defendant is in military service, the court must appoint an attorney to represent him and protect his interest. This attorney, however, will have no power to waive any right of the absent defendant or bind him by his acts. Unless it appears that the defendant is not in service, the court may require, as a condition before any judgment is rendered, that the plaintiff file a bond conditioned to indemnify the defendant, if in military service, against any loss or damage that he may suffer by reason of any judgment should the judgment be thereafter set aside in whole or in part.

If judgment is entered against a person while he is in service or within thirty days thereafter, application may be made for a reopening of the case not later than ninety days after the termination of the service, at which time any meritorious or legal defense may be interposed. Vacating, setting aside or reversing any judgment, however, will not impair any right or title acquired by any bona fide purchaser for value under such judgment.

At any stage thereof, any action or proceeding in any court in which a person in military service is involved, as either plaintiff or defendant, may be stayed by the court during the period of such service or within sixty days thereafter. Likewise the execution of any judgment or order entered against a defendant in service may be stayed and any attachment or garnishment of property, money or debts in the hands of another may be vacated or stayed. If an action for the compliance with the terms of any contract is stayed, no fine or penalty will accrue by reason of failure to comply with the terms of such contract during the period of the stay.

Any stay of any action, proceeding, attachment or execution ordered by the court may be ordered for the period of military service and three months thereafter and subject to such terms as may be just, whether as to payment of instalments in such a manner and at such times as the court may fix or otherwise. Where the person in military service is a co-defendant with

others, the plaintiffs may nevertheless by leave of court proceed against the others. The period of military service, the law provides, shall not be included in the running of any statutes of limitations.

RENTS

No eviction or distress may be made during the period of military service with respect to any premises for which the agreed rent does not exceed \$80 a month, occupied chiefly for dwelling purposes by the wife, children or other dependents of the person in service, except on leave of court. The Secretary of War or the Secretary of the Navy, as the case may be, is empowered, subject to such regulations as he may prescribe, to order an allotment of the pay of a person in military service in reasonable proportion to discharge the rent of premises occupied for dwelling purposes by the wife, children or other dependents of such person. This provision, it will be noted, applies only in connection with the rental of property used chiefly for dwelling purposes. It would seem to be inapplicable to premises used chiefly for office purposes. Legislation has been proposed to extend relief to persons in service in connection with leases executed for offices, but Congressional action on such legislation has not been completed.

INSTALMENT CONTRACTS AND MORTGAGES

No person who prior to the date of approval of the law has received a deposit or instalment of the purchase price under a contract for the purchase of real or personal property from a person who after the date of payment has entered military service may exercise any right or option under the contract to rescind or terminate it or resume possession of the property for nonpayment of any instalment falling due during the period of military service, except by action in a court of competent jurisdiction. The law, however, does not prevent the modification, termination or cancellation of any such contract or prevent the repossession or retention of property purchased or received under the contract, pursuant to a mutual agreement of the parties if such agreement is executed in writing subsequent to the making of the contract and during or after the period of military service of the person concerned. In any court action based on such contract, the court may order the repayment of prior instalments or deposits as a condition of terminating the contract and resuming possession of the contract, may in its discretion order a stay of proceedings for the period of military service and three months thereafter, or may make such other disposition of the case as is equitable to conserve the interests of all parties.

The law specifically provides, however, that no court may stay a proceeding to resume possession of a motor vehicle, tractor or the accessories of either, or for an order of sale thereof, where the property is encumbered by a purchase money mortgage, conditional sales contract or a lease or bailment with a view to purchase, unless the court finds that 50 per cent or more of the purchase price of the property has been paid. In any such proceeding the court may, before entering an order or judgment, require the plaintiff to file a bond to indemnify the defendant against any loss or damage that he may suffer by reason of the judgment should it be set aside in whole or in part.

Similar relief is afforded persons in service in connection with mortgages. The law applies only to obligations originating prior to its approval date and secured by mortgage, deed of trust or other security in the nature of a mortgage on real or personal property owned by a person in military service at the commencement of the period of service and still so owned by him.

INSURANCE PREMIUMS

With respect to life insurance policies, the law provides that on application by a person in military service the Administrator of Veterans' Affairs may guarantee payment of premiums in order to prevent lapsing or forfeiting of policies. Such person may, within one year after leaving military service, pay up premiums unpaid by them and resume payments of regular premiums. If they fail to do so, the policy lapses and the cash surrender value accrues to the government to the extent neces-

sary to meet the cost of premiums which it has guaranteed. The Veterans' Administration is required to issue through suitable military and naval channels a notice for distribution to persons in military service explaining the benefits provided by the law in connection with life insurance policies and to furnish forms to be distributed to those desiring to apply for benefits.

The benefits are applicable to contracts of life insurance up to but not exceeding a total face value of \$5,000, irrespective of the number of policies held by the person, when the contracts were made and the premium was paid thereon before the approval date of the law or not less than thirty days before entering service. The benefits do not apply to any policy on which premiums are due and unpaid for a period of more than one year at the time when application for benefits is made, to any policy on which there is outstanding a policy loan of other indebtedness equal to or greater than 50 per cent of the cash surrender value of the policy, to any policy which is void or which may at the option of the insured be voidable in case of military service, or to any policy which as a result of military service provides for the payment of any sum less than the face thereof or for the payment of an additional amount of premium.

TAXES ON PROPERTY AND INCOME

If a person in service, or any person in his behalf, files with the collector of taxes, or other officer whose duty it is to enforce the collection of taxes or assessments, an affidavit showing (1) that a tax or assessment has been assessed on property as described below, (2) that such tax or assessment is unpaid and (3) that by reason of service the ability of the person to pay the tax or assessment is materially affected, no sale of the property may be made to enforce the collection of the tax or assessment, or any proceeding or action for such purpose commenced, except on leave of court granted on application made by the collector or other officer. The court is authorized to stay such a proceeding or sale for a period extending not more than six months after the termination of the period of military service of such a person.

When by law, however, such property may be sold or forfeited to enforce the collection of the tax or assessment, the person in military service has the right to redeem the property at any time not later than six months after the termination of service, but in no case later than six months after the date when the Soldiers' and Sailors' Civil Relief Act ceases to be in force. If any tax or assessment shall not be paid when due, such tax or assessment due and unpaid will bear interest until paid at the rate of 6 per cent per annum.

The benefits here discussed apply when any taxes or assessments, whether general or special, falling due during the period of military service in respect of real property owned and occupied for dwelling, agricultural or business purposes by a person in military service or his dependents at the commencement of the period of military service and still so occupied by his dependents or employees are not paid. The Secretary of War and the Secretary of the Navy are required to make provision, in such manner as each may deem appropriate for his respective department, to insure notice to persons in military service of the benefits accorded with respect to taxes and the action made necessary to claim these benefits in each case.

MEDICAL TRAINING CENTERS

A U. S. Army Medical Department Replacement Training Center became effective at Camp Joseph T. Robinson, Ark., January 15, bringing to 22,000 the number of medical trainees that can be trained in one training cycle. The Camp Robinson Center will have a capacity of 7,000, the same as the training center at Camp Grant, Ill., while the training center at Camp Lee, Va., has a capacity of 8,000 and the training center at Camp Berkeley, Texas, 4,000. Of this total of 26,000, about 4,000 constitutes overhead personnel, while the remaining 22,000 represent actual trainees for each training cycle. Plans are being made to increase the capacity of the training center at Camp Berkeley and perhaps that at Camp Robinson. At the

With respect to income taxes, the law provides that the collection from any person in military service of any tax on his income, whether falling due prior to or during his period of service, shall be deferred for a period extending not more than six months after the termination of his period of service, if the person's ability to pay the tax is materially impaired by reason of service. No interest on any amount of tax, collection of which is deferred, and no penalty for nonpayment of such amount during such period, will accrue for the period of deferment by reason of such nonpayment.

PUBLIC LANDS

The law provides, in general, that no right to any lands owned or controlled by the United States initiated or acquired under the laws of the United States, including the mining and mineral leasing laws, by any person prior to entering military service shall during the period of service be forfeited or prejudiced by reason of his absence from the land or his failure to perform any work or make any improvements thereon or his failure to do any other act required by or under such laws. Special provisions relate to homesteads, desert land entries, mining claims, mineral leases and irrigation rights. The Secretary of the Interior is required to issue through appropriate military and naval channels a notice for distribution to persons in service explanatory of the benefits of the law in connection with public lands and to furnish forms for use by persons desiring to apply for the benefits.

ADMINISTRATIVE REMEDIES

If in any proceeding to enforce a civil right in any court it is made to appear that any interest, property or contract has since the approval date of the law been transferred or acquired with intent to delay just enforcement by taking advantage of the benefits of the law, the court will enter such judgment or order as might lawfully be entered, the provisions of the Soldiers' and Sailors' Civil Relief Act to the contrary notwithstanding.

In any proceeding under the law a certificate signed (1) by the Adjutant General of the Army as to persons in the Army or in any branch of the United States service while serving pursuant to law with the Army, (2) by the Chief of the Bureau of Navigation of the Navy Department as to persons in the Navy or in any other branch of the service while serving pursuant to law with the Navy, (3) by the Major General Commandant, United States Marine Corps, as to persons in that corps or in any other branch of service while serving pursuant to law with the Marine Corps, or signed by any officer designated by any of them respectively, shall when produced be prima facie evidence as to any of the following facts stated in such certificates:

That the person named has not been, or is, or has been in military service; the time when and the place where such person entered military service, his residence at that time, and the rank, branch and unit of such service that he entered, the dates within which he was in military service, the monthly pay received at the date of issuing the certificate, the time when and the place where such person died in or was discharged from such service.

This law will remain in force until May 15, 1945. If at that time the United States is engaged in war, the law will remain in force until such war is terminated by treaty of peace proclaimed by the President and for six months thereafter.

Army Medical Field Service School, Carlisle Barracks, Pa., a class of 347 medical officers and a class of 231 enlisted men began a course of instruction in field duties. The enlisted men on graduation will receive commissions as second lieutenants in the Medical Administrative Corps.

DR. FRED RANKIN ORDERED TO ACTIVE DUTY

Dr. Fred Rankin, Lexington, Ky., President-Elect of the American Medical Association, has been called to active duty in the Office of the Surgeon General of the United States Army with the rank of Colonel. He will serve as consulting surgeon. He assumes active duty on March 1.

OFFICIAL NOTES

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Program of Meetings to be Held in Chicago
February 16 and 17

The thirty-eighth annual congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, February 16 and 17. The Federation of State Medical Boards of the United States will participate in the congress. The program follows:

MONDAY, FEBRUARY 16, 10 A M

RAY LYMAN WILBUR, M.D., PRESIDING

Medical Care of Civilian Population During War

RAY LYMAN WILBUR, M.D., Stanford University, Calif
Chairman, Council on Medical Education and Hospitals

The Relation of the Chemist to Medicine

VINCENT DU VIGNEAUD, Ph.D., New York
Professor of Biochemistry, Cornell University Medical College

(Topic to be Supplied)

RUFUS C. HARRIS, LL.D., New Orleans
President, Tulane University of Louisiana

The Relation of Pharmacology to Therapy

SOMA WEISS, M.D., Boston
Hersey Professor of the Theory and Practice of Physic, Harvard University

The War, the Colleges and Federal Aid

WILLIAM B. MUNRO, Ph.D., LL.D., Pasadena
Professor of History and Government, California Institute of Technology

The Effect of the War on Medical Education in Canada

J. C. MEAKINS, M.D., Montreal, Quebec
Dean, McGill University Faculty of Medicine

RED LACQUER ROOM

MONDAY, FEBRUARY 16, 2 15 P M

RAY LYMAN WILBUR, M.D., PRESIDING

Current Medical Personnel Problems of the Army

COL. GEORGE T. LULL, M.D., Washington, D. C.
Chief, Personnel Division, United States Army Medical Corps (Representing the Surgeon General of the United States Army)

Medical Education from the Standpoint of the Navy Medical Corps

REAR ADMIRAL ROSS T. MCINTIRE, M.D., Washington, D. C.
Surgeon General, United States Navy

Needs of the Public Health Service for Medical Personnel in National Defense Activities

THOMAS PARRAN, M.D., Washington, D. C.
Surgeon General, United States Public Health Service

Selective Service and Medical Students

BRIG. GEN. LEWIS B. HERSHEY, Washington, D. C.
Director, Selective Service System

The Committee on Medical Preparedness of the American Medical Association

IRVIN ABELL, M.D., Louisville, Ky.
Chairman, Committee on Medical Preparedness of the American Medical Association, and Chairman, Health and Medical Committee of the Federal Security Agency

The Role of Medical Schools in the War

HAROLD S. DIEHL, M.D., Minneapolis
Dean, University of Minnesota Medical School, and Member, Procurement and Assignment Service for Physicians, Dentists and Veterinarians of the Office of Defense, Health and Welfare Services

RED LACQUER ROOM

TUESDAY, FEBRUARY 17, 9 30 A M

JOINT SESSION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS AND THE FEDERATION OF STATE MEDICAL BOARDS

RAY LYMAN WILBUR, M.D. AND J. EARL MCINTYRE, M.D., PRESIDING

Citizenship as Related to Licensure

WALTER E. VEST, M.D., Huntington, W. Va.
President, Public Health Council, West Virginia Department of Health

Access to Hospital Records—Some Legal Aspects

T. V. McDAVITT, Chicago
Bureau of Legal Medicine and Legislation, American Medical Association

The Function of the State Hospital as an Educational and Social Agency

WINFRED OVERHOLSER, M.D., Washington, D. C.
Superintendent, St. Elizabeths Hospital

Accelerating Medical Training in Canada

E. STANLEY RYERSON, M.D., Toronto, Ontario
Assistant Dean, University of Toronto Faculty of Medicine

Summary of the Work of the Council on Industrial Health of the American Medical Association

S. J. SEEGER, M.D., Texarkana, Texas

Teaching of Professional Ethics in Medical Schools

ARTHUR T. McCORMACK, M.D., Louisville, Ky.
State Health Commissioner

The Integrated Course in Anatomy

B. I. BURNS, M.D., New Orleans
Dean, Louisiana State University School of Medicine

RED LACQUER ROOM

THE FEDERATION OF STATE MEDICAL BOARDS

MONDAY, FEBRUARY 16

FEDERATION DINNER

6 30 P M

American Medicine and the National Emergency

MORRIS FISHER, M.D., Chicago
Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Presidential Address

J. EARL MCINTYRE, M.D., Lansing, Mich.
President, Federation of State Medical Boards of the United States

Round Table Discussion ROOM SEVENTEEN

TUESDAY, FEBRUARY 17

FEDERATION LUNCHEON

12 30 P M.

ROOM NINE

TUESDAY, FEBRUARY 17, 2 15 P M

J. EARL MCINTYRE, M.D., PRESIDING

Industrial Health as Related to Licensure

C. O. SAPPINGTON, M.D., Dr. PH., Chicago

Consultant

Licensure Problems in the District of Columbia

GEORGE C. RUHLAND, M.D., Washington, D. C.

Secretary-Treasurer, Commission on Licensure

Have Basic Science Laws Advanced the Practice of Medicine?

THOMAS J. CROWE, M.D., Dallas

Secretary, Texas Board of Medical Examiners

Revision of the Constitution and By-Laws of the Federation of State Medical Boards

T. V. McDAVITT, Chicago

Bureau of Legal Medicine and Legislation, American Medical Association

Business Session

RED LACQUER ROOM

CENTRAL COUNCIL FOR NURSING EDUCATION

MONDAY, FEBRUARY 16, 12 15 P. M.

Luncheon for Lay Boards of Hospitals and Public Health Nursing Organizations

Address

IRVING BLISS SANDER, Ph.D., Evanston, Ill.

President, Northwestern University

GRAND BALL ROOM

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

Maine

Bills Introduced—S. 609X proposes, among other things, to amend the premarital examination law so as to provide that the required physical examination of each party to a proposed marriage may be made also by a physician duly licensed to practice outside Maine who is a graduate of a class A medical school. H. 1953X proposes so to amend the premarital examination law

as to permit any justice of the superior court or any justice of probate in his discretion on the joint application of both parties to a proposed marriage (1) to dispense with the requirements that both parties shall be examined by a licensed physician and shall undergo stated laboratory tests to ascertain the presence of a stated venereal disease or (2) to extend the period following the examination of the physician and the required laboratory test within which the marriage must be solemnized to not more than ninety days after the examination and test.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 327.

CALIFORNIA

Housman Imprisoned.—Dr. Nathan S. Housman, San Francisco, entered San Quentin Penitentiary on November 4 to start serving a one to fourteen year term for perjury which grew out of narcotic violations, newspapers reported on November 5. In his first trial Dr. Housman is alleged to have given perjured testimony on misdemeanor charges of failing to keep proper records of narcotic prescriptions (THE JOURNAL, Dec. 13, 1941, p. 2085).

Ear, Nose and Throat Meeting.—The Western section of the American Laryngological, Rhinological and Otological Society will meet at the Ambassador Hotel, Los Angeles, February 1. The speakers will be:

- Dr. Clarence J. Berne, Los Angeles, Minerals and Water Balance in Surgery.
- Dr. Burrell O. Raulston, Los Angeles, Discussion of Newer Sulfonamides.
- Dr. Howard F. West, Los Angeles, Diabetics Today.
- Dr. Rupert B. Raney, Los Angeles, Late Treatment of Tic Douloureux.
- Dr. Arthur C. Jones, Boise, Idaho, Use of the Diathermy Knife in Submucous Work.
- Dr. Jesse B. Nafziger, Los Angeles, Fractures of Facial Bones Involving Accessory Sinuses.
- Dr. Pierre P. Vide, Los Angeles, Intratemporal Repair of the Facial Nerve.
- Dr. Harrington B. Graham, San Francisco, A Case of Carcinoma of the Epiglottis Treated by the Cyclotron.

COLORADO

Personal.—Thomas D. Kroner, Ph.D., assistant professor of bacteriology, Colorado State College, Fort Collins, has been appointed to a similar position at the Louisiana State University, Baton Rouge, succeeding Charles S. McCleskey, Ph.D., who has been called to active service in the army.

Refresher Courses.—The Colorado State Medical Society will offer a series of refresher courses in Denver, February 16-17. One course will be given at the Denver General Hospital on "Treatment of Fractures and Allied Traumatic Conditions"; one at the Colorado General Hospital, "Acute and Chronic Pulmonary Conditions," and one at the Colorado Psychopathic Hospital, "Psychiatry for the General Practitioner." The series precedes the tenth Annual Midwinter Postgraduate Clinics to be held in Denver, February 19-21.

CONNECTICUT

Personal.—Governor Hurley recently appointed Dr. Charles John Satti Jr., New London, to be commissioner for the second district, under the workmen's compensation laws of the state requiring that one of the five commissioners be a physician. He succeeds Dr. James J. Donohue, Norvich. Dr. Satti graduated at Yale University School of Medicine, New Haven, in 1923. He was secretary of state during the administration of Governor Wilbur Cross.

Lectures on Hearing.—Dr. Norton Canfield, associate professor of otolaryngology, Yale University School of Medicine, New Haven, opened a series of lectures on hearing at the New Haven Hospital, New Haven, January 20, with a talk entitled "Physiology of Hearing Including the Fundamentals of Sound and the Anatomy of the Cochlear Mechanism." On January 22 he discussed "Audiometry"; January 27 he will speak on "Etiology of Deafness," and January 29, "Treatment of Deafness."

Health Service for Industrial Plants.—After a year's study, a program has been approved by the department of preventive medicine of Yale University School of Medicine and the New Haven Medical Association for servicing small industrial plants which have no medical service, except one of emergency. Wherever possible, the plan provides for participation by the family physician, especially in preemployment and periodic examinations. The consultative service is to complement rather than supplement the service available to industry by the bureau of industrial hygiene of the state department of health, and facilities are to be used for clinical teaching by the department of preventive medicine of the university. All

research data accumulated during the service will be used in an effort to decrease the incidence of disease. The project will be reviewed after a trial period of two years to consider its continuance.

DISTRICT OF COLUMBIA

Interprofessional Conference Formed.—Under the auspices of the Medical Society of the District of Columbia an Interprofessional Conference has been organized to bring together representatives of related professional groups for consideration of mutual problems concerning preservation of civilian health in Washington during the war emergency, the Washington Star reported, January 9. In the new setup are the District dental society, the District pharmaceutical association, Graduate Nurses' Association, Health Security Administration and hospital executives. The officers are Dr. Robert Lomax Wells, chairman; Dr. Valentine M. Hess, vice chairman, and Mr. Theodore Wiprud, secretary of the District medical society, secretary. The group plans to hold meetings as often as deemed advisable to keep the cooperating agencies informed on developments bearing on their responsibilities for maintenance of civilian health.

FLORIDA

Public Health Officers.—Dr. William H. Pickett, Jacksonville, state health officer, was elected president of the Florida Public Health Association at its annual meeting in Orlando, succeeding Dr. Leander J. Graves, Tallahassee, director of the Leon County health unit. Other officers are Dr. Leland H. Dame, Sebring, Katherine L. Corbin, Jacksonville, vice presidents; Lord N. Harlow, D.D.S., Jacksonville, president-elect of the Florida Dental Society, secretary-treasurer, succeeding Dr. Edward M. L'Engle, Jacksonville. The 1942 session will be in Miami.

Society News.—The Dade County Medical Society was addressed, November 5, in Miami by Drs. James M. McClamroch and Richard M. Fleming, Miami, on "Gunshot Wounds of the Abdomen."—Dr. Gerry R. Holden, Jacksonville, among others, discussed "Treatment of Menopausal Symptoms in Women with Especial Reference to the Use of Diethylstilbestrol" before the Duval County Medical Society in Jacksonville, November 4.—At a meeting of the Pinellas County Medical Society in St. Petersburg, November 6, Drs. William M. Davis, St. Petersburg, spoke on "Meralgia Paresthetica" and Arthur J. Bieker, St. Petersburg, "New Conceptions in Endocrinology."

Welfare Employees Must Refrain from Politics.—At a meeting of the county welfare board on November 26 new by-laws were adopted providing that "it shall be the policy of the board to require every employee to refrain from political activity," such activity to be cause for dismissal. At the same time it was decided to make a study of ways and means of tightening its free medical services. This action was based on past charges that politics has influenced the admission and treatment of some patients in the county home and hospital, the administration of which was transferred about a month prior to the meeting from the county commission to the newly appointed welfare board.

ILLINOIS

Dr. Kinnaman Goes to New Rochelle.—Dr. Joseph H. Kinnaman, deputy health commissioner and director of maternal and child health, Peoria City Department of Health, has resigned to become health officer of New Rochelle, N. Y. He will be succeeded by Dr. John A. Carswell, Milwaukee, associate executive secretary of the Wisconsin Anti-Tuberculosis Association, effective February 1. Dr. Kinnaman formerly was health commissioner of Topeka, Kan., assistant health commissioner of Cincinnati, instructor at the State University of Iowa College of Medicine, Iowa City, and deputy commissioner to the Iowa State Department of Health in charge of health and health education activities. Dr. Carswell graduated at the University of Toronto Faculty of Medicine in 1928.

Chicago

Meeting on Medical History.—The Society of Medical History of Chicago will be addressed in the Assembly Room at the Institute of Medicine of Chicago, Crerar Library, on January 27 by Drs. Stewart C. Thomson and Leo M. Zimmerman. Their subjects will be, respectively, "The Surgeon-Anatomists of Great Windmill Street" and "The Evolution of Blood Transfusion."

Society News.—Dr. Rettig Arnold Griswold, Louisville, Ky., among others, spoke before the Chicago Surgical Society, December 12, on "Treatment of the Wound in Compound Fractures"; Dr. Hiram Winnett Orr, Lincoln, Neb., discussed the talk.—The Chicago Medical Society was addressed, January

14, by John Howard Mueller, Ph.D., Boston, and Howard J. Shaughnessy, Ph.D., on "Virus and Rickettsial Diseases."—Dr. Delbert K. Judd, among others, addressed the Chicago Laryngological and Otolological Society, January 5, on "Pressure Changes in the Nose and Maxillary Sinus Under Normal Conditions and in Disease."—The Chicago Tuberculosis Society was addressed, January 22, by Drs. Andrew C. Ivy on "Physiology of Respiration in Pulmonary Tuberculosis" and Thomas F. Thornton Jr. and William E. Adams, "Resection of Lung Tissue in the Treatment of Pulmonary Tuberculosis."

Personal.—Five staff physicians of the Hospital of St. Anthony de Padua were recently guests of honor at a banquet at the Edgewater Beach Hotel in view of their long service to the hospital; they are Drs. John J. Sprafka, Frank J. Jirka, Chicago, Fred B. Olentine, Oak Park, Ill., Frank J. Pokorney, Cicero, Ill., and Joseph Zabokrtsky, each of whom was given a jeweled key.—Dr. Walter Schiller, chief of the pathology department at the Cook County Hospital, was named an honorary member of Phi Lambda Kappa at the fraternity's annual dinner, December 30. He will fill the honorary membership held by the late Dr. Jay F. Schramberg, professor of dermatology and syphilology at the University of Pennsylvania Graduate School of Medicine, Philadelphia. There are said to be only four honorary members in the fraternity.—Dr. Joseph B. De Lee was recently honored on his seventy-second birthday at the opening meeting of the Mothers' Aid of the Chicago Lying-In Hospital and Dispensary; Dr. De Lee founded the hospital.

KANSAS

Personal.—Dr. Ransley J. Miller, Topeka, has been appointed acting secretary of the Topeka Board of Health to succeed Dr. Charles B. Stephens, Topeka, who resigned.

Society News.—Dr. Willard M. Allen, St. Louis, addressed the Sedgwick County Medical Society in Wichita, January 6, on "Significance of Abdominal Vaginal Bleeding" and "Clinical Use of the Sex Hormones." The program was sponsored by the Kansas Obstetrical and Gynecological Society.—The Marion County Medical Society was addressed recently by Drs. Charles F. Taylor, Norton, on "Diseases of the Chest Simulating Tuberculosis" and William F. Stone Jr., Norton, "Contact Cases of Tuberculosis."—Dr. Peter T. Bohan, Kansas City, Mo., discussed "Causal Factors in Angina Pectoris and Coronary Infection" before the Pratt County Medical Society in Pratt recently.

LOUISIANA

Public Health Meeting.—Dr. Ford J. A. MacPherson, Baton Rouge, was chosen president of the Louisiana Public Health Association at its annual meeting in New Orleans on December 9. Dr. Reuben A. Brown, New Orleans, was chosen secretary-treasurer. The speakers at the meeting included Dr. John R. Heller Jr., U. S. P. H. S., Washington, D. C.; Ernest C. Faust, Ph.D., acting head of the department of tropical medicine of Tulane University of Louisiana School of Medicine, New Orleans; Dr. John A. Ferrell, New York, of the International Health Division of the Rockefeller Foundation, and Dr. Felix J. Underwood, Jackson, director of the Mississippi State Board of Health. A resolution was adopted at the meeting urging that the state health department provide accident, sickness and hospitalization insurance for its employees.

MAINE

Ear, Nose and Throat Meeting.—The Eastern section of the American Laryngological, Rhinological and Otolological Society met at the Eastland Hotel, Portland, January 15, for the following program:

Dr. Gabriel Tucker, Philadelphia, Observation on Tumors of the Larynx, Benign and Malignant.
Dr. Henry B. Orton, Newark, N. J., Significance of Hoarseness.
Dr. Frederick T. Hill, Waterville, Nasopharyngeal Fibroma.
Dr. Alexander S. MacMillan, Boston, X-Ray of Mastoids.
Dr. Harold G. Tobey, Boston, Acute Otitis Media and Mastoiditis.
Dr. Robert L. Moorhead, Brooklyn, Chronic Otitis Media.
Dr. James G. Dwyer, New York, Otitic Meningitis.
Dr. Champ Lyons, Boston, Chemotherapy in Otolaryngology.

NEBRASKA

Personal.—Dr. Benjamin F. Lorange, Auburn, the oldest physician in Nemaha County, was given a surprise dinner by members of the county medical society to observe his eighty-third birthday, December 6. In addition to carrying on his private practice he is serving as county physician.

New Negro Health Society.—The state medical journal announces that the Nebraska Negro Medical Society filed articles of incorporation with the secretary of state, Frank Marsh, November 20. The object of the new group is to promote health movements among Negroes in Douglas County, it was stated.

Society News.—Dr. George W. Covey, Lincoln, discussed "Vitamin Deficiencies and Anemias" before the Adams County Medical Society, Hastings, recently.—A recent meeting of the Madison Six County Medical Society was addressed in Norfolk by Drs. Edward J. Delehanty, Norfolk, on "Melancholia"; Abram E. Bennett, Omaha, "Electroencephalography as a Diagnostic and Prognostic Aid in Neurology," and Willard C. Brinegar, Norfolk, "The Parkinsonian Syndrome of the Acute Encephalitis."—The Tri-County Medical Society was addressed in Stratton, November 25, by Dr. Frank Lowell Dunn, Omaha, on "A New Approach to Physical Diagnosis of Chest Sounds"; Mr. M. C. Smith, Lincoln, executive secretary of the state medical association, discussed medical problems.

NEW YORK

Society News.—Dr. Henry P. Wagener, Rochester, Minn., discussed "Ocular Evidence of Systemic Disease" before the Buffalo Academy of Medicine in Buffalo, November 12.—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, among others, addressed the one hundred and twenty-first annual meeting of the Medical Society of the County of Monroe in Rochester, December 16, on "American Medicine Prepares."

Graduate Course.—The Medical Society of the State of New York is sponsoring a course to be given before the Fulton County Medical Society alternately at Johnstown and at Gloversville. "The Treatment of Common Diseases" is the theme of the course which has been arranged by Dr. Clayton W. Greene. The program will be presented by the following speakers, all of Buffalo:

Dr. Francis D. Leopold, Results of Modern Methods in the Treatment of Anemia, February 6.
Dr. Louis Maxwell Lockie, Management of Arthritis, Acute and Chronic, February 13.
Dr. Ivan Hekimian, Practical Application of Hormonal Therapy, February 20.
Dr. Earl D. Osborne, Treatment of Common Skin Lesions, February 27.
Dr. Greene, Use of Sulfanilamide and Drugs of That Group, March 6.
Dr. David K. Miller, What Do We Know About Vitamins, March 13.

New York City

Dr. Ladd on Leave of Absence as Dean.—Dr. William S. Ladd has been granted a year's leave of absence as dean of Cornell University Medical College, because of illness. The late Dr. Walter L. Niles who had been appointed acting dean died while in office. Up to January 5 the trustees of the university had not yet appointed another acting dean.

Dr. Pappenheimer Receives Lilly Award.—Dr. Alwin M. Pappenheimer, professor of pathology, Columbia University College of Physicians and Surgeons, was the recipient of a prize of \$1,000 and a bronze medal from the Eli Lilly company for his work in developing a new science combining bacteriology, chemistry, physics and nutrition in the treatment of disease. The presentation took place during the annual banquet of the Society of American Bacteriologists, the American Association of Immunologists and the American Society for Experimental Pathology in Baltimore, December 30. Dr. Pappenheimer received his M.D. degree at Columbia in 1902. He has been associated with the teaching faculty since 1909, becoming professor in 1923. He has done extensive research in infectious and other diseases.

Healthmobile Dedicated.—The Healthmobile of the Brooklyn Tuberculosis and Health Association was dedicated on December 18. The speakers included Borough President John Cashmore of Brooklyn; Drs. Maurice J. Dattelbaum, Brooklyn, president of the Medical Society of the County of Kings; Kendall Emerson, managing director of the National Tuberculosis Association, and Dr. John L. Rice, city health commissioner. The Healthmobile will be used in the health education of children and adults, especially in areas where large groups of defense industry workers are employed. It was planned in cooperation with the board of education and the department of health and produced by the Brooklyn Tuberculosis and Health Association.

Sixty Years a Member of Infirmary Staff.—Dr. Annie S. Daniel, for sixty years a member of the staff of the New York Infirmary for Women and Children, was guest of honor at a dinner given by one hundred graduates of the infirmary. Dr. Daniel, who is in charge of the infirmary's outpatient service, graduated at Woman's Medical College of the New York Infirmary for Women and Children, New York, in 1879. The speakers at the dinner included Drs. Emily Lewi, Emily Dunning Barringer, president of the American Medical Women's Association; Sara Josephine Baker, Bellemead, N. J., consultant for the U. S. Public Health Service; Mary E. Childs MacGregor, Chatham, N. J., and Mary Lee Edward.

Johns Hopkins University School of Medicine, Baltimore, on "The Contraceptive Clinic and Preventive Medicine"; Mrs. Stuart Mudd, director, Marriage Counsel, Philadelphia, "Counseling in Relation to the Clinic Patient," and Mrs. William Talbot, R.N., superintendent, Babies' Hospital, Philadelphia, "Relation of Maternal Health to Other Community Health or Social Agencies." The theme of discussion at the annual dinner will be "Population Planning as a Factor in a Democratic World" with the following speakers: Julian Huxley, British scientist and author; D. Kenneth Rose, national director of the Birth Control Federation of America, Inc., and Mrs. Frank P. Shepard, co-chairman, Metropolitan New York Committee, National Committee for Planned Parenthood.

Priceless British Museum Wrecked—Expression of Gratitude for American Aid.—Admiral Gordon-Taylor of England in December made a tour of the United States and Canada to express the gratitude of the medical profession in Great Britain for the aid given the British people during the bombing of their cities by the Germans. The British War Relief Society, Inc., 730 Fifth Avenue, New York City, has forwarded the Admiral's remarks concerning the destruction of the famous and priceless museum of the Royal College of Surgeons. He said that the Hunterian Museum of the Royal College was utterly wrecked by bombs. Its collection of specimens dealing with anatomy, comparative anatomy and surgical pathology was "undoubtedly the finest museum of its kind in the world and was the Mecca for surgeons from every country and the meeting place of anatomists, comparative anatomists and anthropologists generally.

The museum contained specimens of antiquarian as well as anatomic interest—the only mummy in the world exhibiting gallstones; the skeleton of the Irish giant O'Beirne, for which John Hunter paid in the victim's lifetime what Hunter (a Scot) considered a preposterously large sum. The giant's skeleton escaped intact and its preservation "is due to the aid given us by America."

The museum also possessed the world's finest collection of ornithologic skeletons, but of this collection of three thousand only four remain, although by a curious caprice the specimens surviving were the most valuable of all. They are the skeletons of the moa, the great auk and two solitaires. Sir Frank Colyer's valuable collection of comparative odontology also escaped, but of a large collection of skulls many were damaged and those of greatest value were destroyed. The president and council of the Royal college intend to reconstruct the museum on the old Hunterian lines and they are looking forward to the cooperation of surgeons of the allied powers in this task. The American College of Surgeons, touched by the disaster which befell the museum of an institution which cradled the American college in its infancy, has already made the handsome gesture of sending £2,000 to the Royal college for purposes of immediate relief. This is indeed, the Admiral said, a most friendly and greatly appreciated act on the part of surgeons from this side of the Atlantic.

Before the bombing began there were no fewer than a quarter of a million specimens. After the disaster the immediate problem confronting college authorities was how to salvage and convey to safety what remained of the collection; means of transport were extremely scarce. Appeal was made to the American Ambulance Service in Britain maintained by the British War Relief Society in New York. Mr. Glenn Osborne of that service immediately came to the rescue, providing a fleet of ambulances in which seventy-eight loads of specimens were removed to safe places. It is notable that out of twenty-four thousand fragile specimens so moved only six were at all damaged during transport. "That is a tribute not only to the sound construction of the vehicles but to the skill and care of the women volunteer drivers. We have every reason for being grateful to the service and to its volunteer personnel for aid not only to museum specimens but to the living. The organization first proved its worth during the evacuation of Dunquerque. Of its aid then I had personal experience. Sick and wounded soldiers were being landed, often from small boats, at all sorts of out of the way points on the southeastern coast. Many of these evacuees needed immediate medical attention, which was provided by such means as were locally available. But this emergency assistance had to be supervised and supplemented by more expert aid. In transporting professional surgeons to the more hard pressed areas and in moving the injured inland, the cars of the American Ambulance Service in Britain did valiant work as I well know. I have reason to be especially grateful for aid rendered to myself in moving about under stress in my consultative capacity.

"The British people will never forget the help so willingly extended by the American people at that time. It should tend to bind us forever with a tie of mutual respect and affection that no evil power now or in the future can break."

LATIN AMERICA

First Congress of Internal Medicine.—The first Mexican Congress of Internal Medicine will be held in Mexico City, May 3-10, under the auspices of the president of Mexico and the Departments of Education and Public Health and with the cooperation of the medical societies of Mexico and the National University. The congress will be made up into various sections covering a wide range of subjects in this specialty.

Time Changed for Pan American Congress on the Child.—The eighth Pan American Congress on the Child will be held in Washington, D. C., May 2-9, instead of March 28-April 4. The session will be divided into three sections: Prevention of Diseases of Children and Medical Care, Education and Recreation, and Social Aspects of Protection of Children and Economical Help Through the Family. Papers to be presented must be received by the secretary before February 28 at the following address: Secretaria de Comité Uruguayo, Instituto Internacional Americano de Protección a la Infancia, Avenida 18 de Julio, No. 1648 (3er. piso), Montevideo, Uruguay.

CORRECTION OF CORRECTION

The Addis Count.—Dr. Ernest B. Zeisler of Chicago writes that an error is present in the correction entitled "Calculation of the Addis Count," which appears on page 2265 of *THE JOURNAL* of Dec. 27, 1941. Dr. Zeisler says that in the twelfth line of this correction the "0.4 sq. mm." should be "0.4 cu. mm.," and that in the thirteenth line the words "per cubic centimeter" should be deleted.

Government Services

Examination for Student Dietitians

The examination for student dietitians, which was to be held December 31, has been delayed until January 31. The announcement states that the salary for the student will be \$420 a year, less a deduction of \$330 a year for subsistence and quarters during the training period. Persons successfully completing the training course at the Army Medical Center will be eligible for retention in the service in dietitian positions paying \$1,800 a year. Communications should be addressed to the U. S. Civil Service Commission, Washington, D. C.

Dr. Thompson Named to Newly Created Health Service Position

Dr. Lewis R. Thompson, Washington, director of the National Institute of Health and assistant surgeon general in charge of scientific research, has been appointed chief inspecting officer of the U. S. Public Health Service, a new position established in the Office of the Surgeon General. As a result of the increased demands on the public health service because of the expansion of programs of civilian and military defense, the field activities of the district offices of the public health service and its liaison officers in the army corps areas have been consolidated under one head. Dr. Rolla E. Dyer has been named to succeed Dr. Thompson as assistant surgeon general in charge of the Division of Scientific Research and as director of the National Institute of Health, effective February 1. Dr. Thompson graduated at Louisville Medical College in 1905 and was commissioned in the public health service in 1910. In June 1917 Dr. Thompson was detailed as principal assistant of the director of health and chief quarantine officer of the Philippine Islands, succeeding to the position of chief quarantine officer two years later. In April 1921 he became the first chief of the newly established Office of Industrial Hygiene Investigations in the Division of Scientific Research, which is now an important division of the National Institute of Health and the coordinating agency for all industrial hygiene activities in the national defense program. He has been assistant surgeon general in charge of the Division of Scientific Research since August 1930. Dr. Dyer graduated at the University of Texas School of Medicine, Galveston, in 1915. On completion of his internship he was commissioned as assistant surgeon in the public health service, where he has advanced through the various grades. He has been assistant director of the National Institute of Health since 1922 and since 1937 also chief of the division of infectious diseases at the institute.

The Polish Faculty of Medicine at Edinburgh

A prominent example of German barbarity is the destruction of universities. From the Polish universities the professors, when not done away with quickly, were sent to notorious concentration camps. Libraries were closed and their books confiscated. For the large number of Polish physicians and medical students who found refuge in this country a Polish faculty of medicine has been established within the University of Edinburgh. At the Royal Society of Medicine the dean of the faculty, Prof. A. T. Jurasz, delivered an address on the subject. In July 1940 the remnant of the Polish army, which included many medical officers, was brought to Britain. In view of the large number of Poles in Scotland, Colonel Fortescue, deputy director of medical services, Scottish command, sought a means of occupying and refreshing the knowledge of the physicians among them. He consulted Professor Crew, who was in command of a military hospital. The latter arranged for batches of twenty Polish medical officers at a time to be attached to that hospital for periods of a fortnight. Further arrangements were made with the faculty of medicine of Edinburgh University and with the Royal Infirmary of Edinburgh whereby Polish medical officers might be spread among different departments and clinics, but linguistic difficulties impaired the success of the scheme. As many of the Polish medical officers had held academic positions in the Polish universities and there were among the troops many medical students whose studies had been interrupted by the war, Professor Crew suggested that these professors should be given facilities at Edinburgh to teach their countrymen in their own language and that the undergraduates should be allowed to complete their curriculum and graduate. The authorities of Edinburgh University readily granted the necessary hospitality, and the heads of departments of the faculty of medicine placed their resources at the disposal of their Polish colleagues. The board of the famous Royal Infirmary agreed to open their lecture rooms and wards to Polish professors, lecturers and students. More recently these have been given accommodation in the municipal hospitals. The secretary of Edinburgh University and the legal adviser to the Polish government worked out the constitution of the new school.

The teaching staff comprises six professors, seven lecturers and ten other specialists. Edinburgh professors have taken subjects for which Polish lecturers were not available. The curriculum and standards of teaching and examination are the same as those of the faculties of medicine of Polish universities. A Polish hospital named after Paderewski has been organized in the grounds of the Western General Hospital, Edinburgh. It has been equipped with American help and is intended for the treatment of Polish civil as well as military cases. It is staffed by members of the Polish faculty of medicine and contains eighty beds and an outpatient department. Surgical beds and the operating room and x-ray department of the Western General Hospital have been placed at the disposal of the Poles.

The school began with seventy-seven students, of whom forty-seven are serving in the Polish forces. Some thirty had finished their studies in Poland but had not passed their examinations, and refresher courses were arranged for them. Two Scottish professors—Sydney Smith and T. J. Mackie—examine in forensic medicine and bacteriology respectively. For the second academic year there are one hundred and twenty students of whom five are Czechs.

New Wartime Feeding Plans for Children and War Workers

In the House of Lords Lord Woolton, minister of food, stated that the government was anxious to extend the feeding of children in schools by local education authorities and would make grants for the purpose. War conditions had altered the nature of the problem. We were all now, as a result of the equalizing effect of the ration book, living on a diet mainly influenced by the extent of the domestic ration. This was based on the average need of the average family and was not designed to meet the needs of special classes, who might find the diet insufficient. This particularly held for children, who needed more than the average of body-building foods. At present there were five million children in the elementary and secondary schools, and only three hundred thousand of these receiving meals in school. We could now assure local education authorities that a sufficiency of food would be forthcoming, whatever the demand. Priority supplies had been arranged to enable schools to serve the balanced meals recommended by the medical and scientific advisers for maintaining the growth and health of school children. Extension of the milk in schools scheme would also come into operation at once. (It was stated next day in the House of Commons that every local authority in the country received instructions on the new drive for the feeding of school children. It is expected that one million school children will receive hot midday meals within the next twelve months.)

In wartime, said the minister, it was the duty of the government to see that there was supplied food adequate for maintaining the physical strength of the workers producing munitions for our allies and ourselves. This could be done thanks in large measure to the aid given by the United States on the one hand and by our farmers on the other. Food would be allocated to industrial canteens according to needs in three groups—for workers requiring meals of the most substantial kind, for those catering for other workers and for those who serve the rest of the population. Heavy workers required more meat, fish or cheese than office workers. In some forms of work more sugar was required than in others.

Lord Horder said that this was a red letter day in the annals of children's nutrition. He envied Lord Woolton because in years to come it would be to his credit that he had adopted the principle of preventing child nutrition being sacrificed during wartime by the bold move of increasing considerably the provision of standard meals at school. The organizing would not be easy; everybody must help.

Motor Cyclists Should Wear a Crash Helmet

In the *British Medical Journal* a surgeon, Mr. Hugh Cairns, has made a strong plea for the wearing by all motor cyclists of a crash helmet, such as is now worn by them when they race. During the first twenty-one months of the war 2,279 motor cyclists and pillion passengers were killed on the roads, 21 per cent more than during the corresponding months of peace. Head injury was present in over 90 per cent. The helmet recommended consists of an outer shell of some firm substance shaped like an inverted pudding bowl. It is lined with a series of web slings attached to the base and fitting snugly on the rider's head. The helmet is also retained in place by a chin strap. In 15 cases, seen by Mr. Cairns, of injury while wearing a crash helmet the effects were unusually mild except 1 in which a frontal fracture had been sustained. In all complete recovery took place. In most of them there was considerable damage to the helmet. It did not invariably prevent fracture of the skull, but it probably prevented the fracture from spreading as far as it otherwise would have done. In frontal injuries when there is no crash helmet the fracture

usually extends backward along the roof of the orbit and into the accessory nasal sinuses, whereas in the case mentioned the fracture was limited to the area of damage of the crash helmet. The brain damage in all cases was remarkably slight, as judged by absence of neurologic signs and by the promptness and completeness of the recovery of intellectual functions.

United States Ambulances for Wounded Airmen: Electrically Heated Blankets

The duke of Kent received in London from the American ambassador, Mr. J. G. Winant, two motor ambulances fitted with electrically heated blankets. These represent a much larger number of a new type, of which over thirty have been received and are in service overseas. Others are on their way. The duke of Kent said that road transport in winter tested the skill of nurses in keeping the patients comfortable, and it had appeared to the British-American Ambulance Corps that the only solution was electric heating, by which the blanket could be kept at an even temperature. Mr. Winant described the gift as evidence of the support of every section in the United States. Next to fighting for a great cause was the opportunity of helping those who risked their lives for it.

The Medical Profession in New Zealand and Social Security Medical Services

Controversy regarding changes in the medical service in New Zealand has gone on for many years. In this small community of 1½ million people and about six hundred and fifty practicing physicians the standard of practice is high, and it is solely that this high standard might be maintained that the present deadlock between members of the profession and the government has developed. The New Zealand hospital system in the early days developed along the line that the provision of medical services for the sick poor was not a matter for private benevolence but a community responsibility. Such an attitude inevitably led to socialization of hospitals, and this process is now almost complete. The socialization of medical practice was first brought to light as a concrete proposal in 1927, when the New Zealand representative to the League of Nations signed a draft convention whereby the signatories undertook to introduce discussion of national health insurance into their legislatures. In 1934 the Hospital Boards Association issued tentative draft schemes for New Zealand, but none of these schemes allowed for the difference in character and distribution of population in New Zealand as distinct from that of Europe. In 1935 the Council of the British Medical Association set up the National Health Insurance Committee to investigate the position. This committee interviewed Dr. G. M. McLeary, Dr. Kaye Le Fleming, Dr. H. Guy Dain and later Sir Henry Brackenbury. After its review it concluded that further advances on the general lines of health insurance systems adopted by other countries would not meet New Zealand conditions.

At the end of 1935 the labor government swept into power, the strongest plank in its platform being national health insurance. Cooperation was immediately offered by the profession, which asked for the confidence of the government in any proposals it might decide on. The government set up an investigation committee in its first year of office and called evidence from various organizations. This committee was formed on a purely party basis, no one member possessing the technical or professional knowledge necessary to the successful delineation of such a scheme. However, the British Medical Association made representations, reviewing existing organizations, advocating greater attention to preventive medicine and research with complete service for those whose financial circumstances pre-

cluded the payment of medical fees and a contributory form of insurance for all others to enable them to provide against hospitalization, with laboratory and specialist fees. Such ideas were unacceptable to the government, which in turn expressed its intention of introducing a universal free medical service based on free general practitioners and specialists with vague references to payment of £1 per head of population plus mileage expenses, thus introducing in the view of the profession an undesirable degree of control of both doctors and public.

In 1937 Sir Henry Brackenbury, an advocate of national health insurance, visited New Zealand and after consultations with crown ministers and the association reviewed conditions, eventually admitting that, in addition to a free system being undesirable, the profession could not offer the public the present high standard of service for less than £1.11.6 per head of population, excluding specialist services. Battle was then joined. At the request of the minister of health a carefully drawn statement was prepared by the British Medical Association, explaining the curiously personal nature of a doctor's work. Medical service does not lend itself readily to terms of contract like the supply of a definite number of standard articles or the giving of so many hours of specific work. Modern methods of mass production and the moving work platform are not suitable for medical work. It became obvious at this stage that political considerations rather than those of practical necessities were to be paramount, one minister remarking that the association's scheme would "leave the doctors free to fix their own fees over a greater part of the work." Complete socialization and political control was obviously the government's aim. A parliamentary bill was drawn up on the lines of a universal scheme. No consultation with the profession was held, but the bill was passed in December 1938, after which negotiations between the association and the government ceased. Nevertheless preparations for the introduction of the scheme passed into abeyance, no explanation being forthcoming. With unconscious and rather satirical humor, the first benefit introduced was free mental hospital treatment, commencing on April 1, 1939, following which, in spite of protests by the association, a contract for maternity services was offered to the general practitioners. This failed. After many weeks a compromise was effected by allowing those doctors who so wished to continue the practice of obstetrics by private arrangement among patients willing to bear their own costs. The hospital benefit was introduced in July 1939. It was agreed by the profession that there could be no question of withdrawing honorary staffs, the feeling being that when hospitals ceased to be exclusively benevolent institutions it was no longer incumbent on the profession to give honorary service, especially as they were now open to all, exclusive of means. Consequently it was agreed to change to the part time stipendiary service. There were regrets—a loss of idealism as against the introduction of the wage earner's attitude of mind. With the passage of honorary service, medicine in New Zealand sustained a loss.

In the meantime war broke out and it became clear that the demands of war service were reducing the number of doctors available for civil practice. With free maternity and hospital benefits it was expected that the government would have the good sense to delay proposals for general practitioner service. But in February 1940 the government resumed negotiations with the association. The scheme was implemented by the drawing up of contract forms to be signed by both patient and doctor, the first of which were issued in March 1941. In spite of such cavalier treatment, the attitude of the association was clear. A deadlock had arisen. Contracts had been issued but not signed. After six weeks forty-nine doctors were reported to have signified their willingness to work the scheme, although they had not necessarily signed contracts. Now another compromise has been reached. A universal general practitioner

service, estimated to cost £1,400,000 a year, will commence on November 1. The service will not include specialist treatment, administration of anesthetics, examinations for insurance purposes, treatment of venereal disease or extraction of teeth by a doctor. The New Zealand public has been paying for the service since 1939 by a 1 shilling in the pound wage tax and a quarterly levy of 5 shillings. The Auckland branch of the British Medical Association states that doctors will issue receipts to patients, who may obtain refunds from the health department. Fixed charges are 7/6 for ordinary consultations and 12/6 for night or Sunday consultations plus 1/3 per mile for traveling. Members of the profession are asking for a non-political commission to investigate the problem of providing the best health services for New Zealand. Meanwhile, it has become increasingly evident that there is a serious shortage of qualified men to fulfil both the ordinary demands of civilian care and the special needs of the war.

Fertility of Patients with Mental Diseases

The question of the fertility of patients with mental diseases was discussed by Dr. E. E. Krapf of the Hospicio de las Mercedes in Buenos Aires before the Sociedad Argentina de Criminología. It concerned a critical evaluation of the German sterilization measures. Krapf said that there has been an alarming increase in socially unfit persons. One possibility to check this increase consists in the energetic reduction of the hereditary transmission of mental diseases. In the United States, in Switzerland and in Scandinavia legally regulated attempts have been made in this direction. The German sterilization law of 1933, a compulsory law, not only refers to mental defectives but is later to be extended to other persons whose propagation seems undesirable, such as habitual criminals and vagabonds.

In drawing up this law, it has not been considered that disease is rarely transmitted directly. The number of the schizophrenic, for instance, is estimated at 1 per cent of the German population, whereas the number of heterozygotes, who are apparently healthy but are capable of transmitting schizophrenia, is estimated by Rüdin at 19 per cent. These, who are the more dangerous, cannot be sterilized without leading to racial suicide. The Munich psychiatrist Bumke declared in 1939 that the relative increase in mental defectives is due to their greater fertility compared to that of healthy subjects. On the basis of these opinions Krapf contends that the central problem of every objective discussion of eugenic sterilization is the problem of absolute and relative fertility of mental defectives. The justification of compulsory sterilization will stand and fall with further investigations on this problem.

The percentage of hereditary cases is not yet known with desirable exactness, although the number of hereditary cases is doubtless quite high. Earlier investigations, which are concerned only with the feeble-minded and with the fertility of their fathers, are not conclusive for various reasons. However, an investigation by Dr. Juda at Rüdin's Munich institute demonstrated that the difference between the fertility of feeble-minded and normal subjects is really slight and that with exact statistical evaluation it disappears almost completely; that is, if the higher infant mortality in the families of the feeble-minded is taken into consideration. The fertility of the near relatives of the feeble-minded shows an analogous behavior. Thus these investigations, which, in view of their origin, are certainly decisive for the problem of sterilization in Germany, do not indicate a danger from progressive increase of the relative number of feeble-minded.

Statistically evaluated investigations on schizophrenia, conducted by the Swedish physician Essen-Möller at Rüdin's insti-

tute, disclosed that the fertility of the schizophrenic amounts to hardly 50 per cent of that of the normal population. Their low fertility is corroborated also by other investigations. Computations based on a frequency of 1 per cent, assuming a recessive monohybrid type of heredity lead to the conclusion that a complete sterilization of all the schizophrenic for twenty generations, that is, for six hundred years, would reduce their number to 10 per cent of the present number. According to results obtained by Essen-Möller the time required would be one thousand two hundred years, and even this computation is regarded as too optimistic if a considerable reduction of schizophrenia is to be obtained by sterilization. It was observed also that the number of schizophrenic sons of schizophrenic fathers is extremely small and that the larger number of these patients are the offspring of apparently healthy fathers, so that sterilizing intervention is impossible.

In persons with manic depressive insanity the investigations of Essen-Möller disclosed a fertility that was about identical with that of the normal population. Although a large percentage of these patients are the offspring of fathers with the same defect, other reasons make the suppression of this disease by sterilization impossible.

The fertility of the epileptic was disclosed by Essen-Möller to be less than that of normal persons and hardly higher than that of the schizophrenic. Moreover, the mortality of persons with epilepsy is eight times as high as that of normal persons, so that their propagation is greatly restricted. There is here the same tendency of self elimination as in case of schizophrenia, and here, as there, the direct heredity is not frequent. Thus there is only a slight possibility that the sterilization of epileptic fathers will produce a considerable reduction in the number of these patients.

Krapf also considers the fertility of habitual criminals. Again investigations in Rüdin's institute by F. Stumpfl demonstrated that habitual criminals are much less fertile than are occasional criminals and the average population, to which must be added the higher infant mortality of the first. This goes so far that Stumpfl speaks of the biologic self elimination of habitual criminals and their families.

None of the categories mentioned here have a higher than normal fertility, and therefore the aforementioned assertion of Bumke is not correct. Furthermore, it must be considered that before the defect is diagnosed and thus before there is a possibility of sterilization 67 per cent of the sons of the schizophrenic and 90 per cent of the sons of those with manic depressive insanity have already been born. This eliminates other foundations for sterilization and for this entire conception of public hygiene which only undermines confidence in the physician without promoting the welfare of the state. This investigation of Krapf has demonstrated definitely that it is impossible to avoid mental diseases by the systematic elimination of hereditary factors.

Marriages

ROY STINSON BIGHAM JR., Charlotte, N. C., to Miss Glenna Elvin Gochenour in Charlottesville, Va., Nov. 15, 1941.

JOSEPH ENNALLS MUSE JR., Baltimore, to Miss Anne Marie Gorman at Takoma Park, Md., Nov. 20, 1941.

GUSTAVUS A. PETERS, Franklin, Ind., to Miss Hilda Hartman in Rochester, Minn., Oct. 10, 1941.

RANDALL F. WHITE, Portland, Ore., to Mrs. Thelma Davenport of Eugene in October 1941.

EDWIN BURTIS AYCOCK to Miss Jean Hodges, both of Greenville, N. C., in November 1941.

DANIEL H. SHEERAN to Miss Rita Mary McGinnis, both of Flint, Mich., Sept. 27, 1941.

HARDIE B. ELLIOTT JR. to Miss Wilhelmina Meyer, both of Flint, Mich., Oct. 2, 1941.

Deaths

LeRoy S. Peters ⊕ Albuquerque, N. M.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; member of the American Association for Thoracic Surgery and the American College of Chest Physicians; fellow of the American College of Physicians; for many years a director of the National Tuberculosis Association; past president of the American Sanatorium Association and the Southwestern Medical Association; associate medical director of the Cottage Sanatorium, Silver City, from 1909 to 1913 and the Albuquerque Sanatorium from 1913 to 1917; medical director of the St. Joseph Sanatorium from 1917 to 1925; aged 59; died, Dec. 17, 1941, of coronary occlusion.

Everett A. Sheldon, Bellflower, Calif.; College of Medical Evangelists, Loma Linda, 1925; member of the California Medical Association; fellow of the American College of Surgeons; instructor in surgery at his alma mater; member, visiting staff, Long Beach Community Hospital, Long Beach; junior attending surgeon, Los Angeles County Hospital, Los Angeles; aged 40; on the courtesy staff of the White Memorial Hospital, Los Angeles, where he died, Dec. 2, 1941, of Banti's syndrome and hemorrhages from esophageal varices.

William Sturgis Thomas ⊕ New York; National University Medical Department, Washington, D. C., 1892; was president of the New York State Society of Pathologists; veteran of the Spanish-American and World wars; was made a Chevalier of the Legion of Honor by the French government; for many years served on the staff of St. Luke's Hospital in various capacities; in 1939 member of the advisory committee of the New York World's Fair; author of several books; aged 70; died, Dec. 21, 1941.

Laverty H. McCuskey, Moundsville, W. Va.; College of Physicians and Surgeons, Baltimore, 1897; member of the West Virginia State Medical Association; past president of the Marshall County Medical Society; member of the draft board during the World War; for many years county school physician; aged 71; died, Dec. 18, 1941, of coronary thrombosis.

Eugene Madison Parker ⊕ Houston, Texas; University of Illinois College of Medicine, Chicago, 1934; member of the Radiological Society of North America, Inc., and the American College of Radiology; on the staff of St. Joseph's Infirmary; aged 38; died, Dec. 4, 1941, in Granite City, Ill.

Stephen Aloysius Yesko, Washington, D. C.; Georgetown University School of Medicine, Washington, 1922; at one time assistant professor of anatomy at his alma mater; aged 45; died, Nov. 5, 1941, in the Garfield Hospital of gastric hemorrhage, esophageal varices and cirrhosis of the liver.

Robert Vandenberg White, Scranton, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1900; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 64; on the staff of the Hahnemann Hospital, where he died, Dec. 8, 1941.

Sidney L. Scott, Fredericksburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1901; New York Homeopathic Medical College and Hospital, New York, 1903; member of the Medical Society of Virginia; aged 62; died, Dec. 16, 1941, of coronary thrombosis.

Peter Augustine Reque ⊕ Brooklyn; University of Vermont College of Medicine, Burlington, 1896; fellow of the American College of Physicians; served during the World War; aged 72; died, Dec. 4, 1941, in the Long Island College Hospital of coronary occlusion.

Winfred Bryant Post ⊕ Carthage, Mo.; Missouri Medical College, St. Louis, 1897; member of the American Academy of Ophthalmology and Otolaryngology; on the staff of the McCune-Brooks Hospital; aged 70; died, Dec. 22, 1941, of coronary occlusion.

William Rhinehart Schick, Chicago; University of Illinois College of Medicine, Chicago, 1940; first lieutenant in the medical reserve corps of the United States Army; aged 31; was killed, Dec. 7, 1941, in action during the Japanese raid on Pearl Harbor.

Bina Seymour, Springfield, Mass.; New York Medical College and Hospital for Women, New York, 1913; aged 71; died, Dec. 8, 1941, in the Springfield Hospital of rupture of the abdominal aorta resulting from the pressure of a large calcareous plaque.

Richard Redner Rall ⊕ Lieutenant (j. g.) U. S. Navy, Pearl Harbor, T. H.; Loyola University School of Medicine, Chicago, 1934; entered the Navy Aug. 5, 1936; aged 32; was killed, Dec. 7, 1941, in action during the Japanese raid on Pearl Harbor.

William Samuel McCormick, Arlington, Tenn.; Memphis (Tenn.) Hospital Medical College, 1885; at one time justice of the peace; formerly chairman of the county court and of the county school board; aged 77; died, Dec. 16, 1941, in Memphis.

George M. Rutledge, Ste. Genevieve, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1889; member of the Missouri State Medical Association; aged 78; died, Dec. 10, 1941, in the Alexian Brothers' Hospital, St. Louis, of pneumonia.

Walter Fairbanks Sawyer, Fitchburg, Mass.; Harvard Medical School, Boston, 1893; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; consulting surgeon, Burbank Hospital; aged 73; died, Dec. 8, 1941.

Hervey Barbour Scott, Irvine, Ky.; Hospital College of Medicine, Louisville, 1906; at one time assistant clinical professor of psychiatry at the University of Louisville School of Medicine; aged 62; died, Dec. 14, 1941, of lobar pneumonia.

William R. Williams, Greenville, Ind.; University of Louisville (Ky.) Medical Department, 1881; aged 84; died, Dec. 1, 1941, of injuries received when struck by an automobile as he was attempting to cross the street.

Louis Stockton Walton ⊕ Altoona, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; past president of the Blair County Medical Society; served during the World War; aged 64; died, Dec. 5, 1941.

Archibald Herbert Martin ⊕ Lynn, Mass.; College of Physicians and Surgeons, Boston, 1896; for many years on the staff of the Lynn Hospital; aged 69; died, Dec. 13, 1941, in the Palmer Memorial Hospital, Boston.

Clarence Henry Wieneke, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; member of the Illinois State Medical Society; aged 51; died, Dec. 15, 1941.

George Walter Warren, Washington, D. C.; Baltimore University School of Medicine, 1892; member of the Medical Society of the District of Columbia; aged 78; died, Dec. 15, 1941, in Wilson, N. C., of pneumonia.

William A. Phelps, Thebes, Ill.; Kentucky School of Medicine, Louisville, 1884; member of the Illinois State Medical Society; aged 86; died, Dec. 7, 1941, of cerebral arteriosclerosis and carcinoma of the face.

John Franklin Scarborough, Port Gibson, Miss.; Memphis (Tenn.) Hospital Medical College, 1910; member of the Mississippi State Medical Association; served during the World War; aged 61; died, Dec. 11, 1941.

William O. Ziemer, Cleveland; Western Reserve University Medical Department, Cleveland, 1904; on the staff of the Lutheran Hospital; aged 59; died, Dec. 2, 1941, of coronary sclerosis and myocardial infarction.

Franklin Ivan Flagg ⊕ Boston; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1921; was on the staff of the Boston State Hospital; aged 54; died, Oct. 10, 1941, of coronary thrombosis.

J. M. Teter, Beaver, W. Va.; Baltimore Medical College, 1896; member of the West Virginia State Medical Association; aged 68; died, Dec. 10, 1941, in the Raleigh General Hospital, Beckley.

Austin E. Popham, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1904; served during the World War; aged 62; died, Dec. 8, 1941, of cerebral hemorrhage and hypertension.

Russell Burton Main, Norris City, Ill.; Columbian University Medical Department, Washington, D. C., 1900; served during the World War; aged 64; died, Dec. 26, 1941, of heart disease.

DeWitt Clinton Smith, Dunkirk, Ohio; Miami Medical College, Cincinnati, 1874; aged 93; died, Dec. 5, 1941, in the McKittrick Hospital, Kenton, of angina pectoris.

Hilmar Carl Schmidt, North Hollywood, Calif.; Hering Medical College, Chicago, 1908; aged 66; died, Dec. 7, 1941, of coronary occlusion.

D. Manners Washburn, New Richmond, Ind. (licensed in Indiana in 1897); aged 90; died, Dec. 11, 1941.

Bureau of Investigation

FRAUDULENT "CURES" FOR ASTHMA, HAY FEVER AND SINUS DISORDERS

Post Office Department Debars Five of These from the Mails

In the twelve months from June 1940 through May 1941 five "cures" for asthma, hay fever and sinus troubles were declared fraudulent by the Post Office Department and banned from the mails.

As-Ma-Norm—Under the title The Norm Company one Otto Beck of Englewood, N. J., sold this nostrum through the mails as an asthma treatment. Among the representations made in connection with its sale that the Post Office Department alleged were false and fraudulent were that it would afford effective relief in bronchial asthma, that it contained no harmful drugs and that its sale was approved of by the Post Office. Accordingly Beck was cited to show cause why a fraud order should not be issued against his business. He neither appeared at the hearing of the case nor sent a representative, though previously he had written the department that he was willing to abandon the enterprise. At the hearing a government chemist testified that the treatment came in gelatin capsules each of which contained 6.99 grains of yellow brown powder consisting of 4.48 grains of potassium chloride, 0.27 grain of ephedrine sulfate and the rest was rhubarb. An expert medical witness for the government brought out the fact that bronchial asthma is a symptom complex characterized by hypersensitivity to certain allergens or substances that produce bronchial spasms. These allergens may be ingested or inhaled or may be actual proteins existing in such in the victim's body. He further testified that the ingredients of As Ma Norm are common drugs whose therapeutic effects and limitations are familiar, and that rhubarb and potassium chloride offer no relief in asthma. He showed further that ephedrine, even when given in the proper dosage, which is from four to seven times the amount contained in As Ma Norm capsules, is only a temporary palliative employed in certain instances for the treatment or relief of asthma and that the amount of ephedrine obtained by users of As Ma Norm when taken according to directions is so small as to be inconsequential in the treatment of asthma. The witness further brought out, among other things, that ephedrine, instead of being a harmless drug, is deleterious to persons suffering from high blood pressure, diabetes, thyroid disturbances and heart trouble. On May 10, 1941 the Post Office issued a fraud order against the Norm Company and its officers and agents.

Dr. Hayle's Method—This piece of quackery, also known as "Dr. Hayle's Australian Method" and "Dr. Hayle's Treatment," apparently originated with a C. R. S. Woolams of Auckland, New Zealand, who operated under the names Charlton Sinclair, Limited and Charlton Sinclair, Manager. Its American agent was a Sylvan Mallinson, who did business from Los Angeles under the names of Gilbert H. Haddon and the Thyson Company. It was sold under the representations that it contained no harmful drug and that, when used as directed, it would within five minutes afford "amazing" and "magic-like" relief from asthma and hay fever attacks and remove the causes of these, besides preventing further attacks. The Post Office investigation revealed that the "treatment" was made up for Mallinson by a Los Angeles pharmacy and sold in three parts: a liquid "Dr. Hayle's Prescription H. L. 67," composed essentially of potassium iodide, 9.8 grains per hundred cubic centimeters, a powder, "A. C. 43," consisting chiefly of potassium nitrate and sodium sulfate, carbonate and bicarbonate, and a saline, "B. 30," to be used in the nostrils, which contained camphor, menthol and eucalyptus in a petrolatum base. With these medicines went some "diet advice" directing the customer to eat sparingly of starchy foods and take liberal portions of fruits, vegetables and certain meats. The government presented expert medical testimony to the effect that one part of the treatment, instead of being harmless, contained potassium iodide, which might make its use dangerous in cases of asthma caused or complicated by tuberculosis, that the combination was not an amazing Australian formula, since its ingredients were all common drugs, and that it would not cure asthma or hay fever. Accordingly a fraud order was issued on June 4, 1940 against all the names under which the concerned operated.

Minus-Sinus—This was promoted by a Mrs. V. Herreck, who operated under the name Approved Products, Ltd., Oak Park, Ill. A government chemist who analyzed it reported that it consisted of 49.53 per cent of sugar, 28.2 per cent of boric acid and 23.2 per cent of starch. It was to be snuffed into each nostril from the palm of the hand morning and night. Mrs. Herreck was cited to appear at a government hearing and show cause why a fraud order should not be issued against her business, but instead she merely filed a written answer which was in effect a general denial of the charges. At the hearing the government presented expert medical testimony showing that many factors may underlie sinus troubles and that since such disorders must be treated according to their causes no one method is of value in a large number of cases. Hence for Mrs. Herreck to represent her treatment as generally effective was declared to amount to false and fraudulent representation. A fraud order debarring the Approved Products, Ltd., and its officers and agents from the mails was issued on July 9, 1940 by the Post Office Department.

Orbert Asthma Treatment—From La Feria, Texas, a Mrs. E. G. Orbert, a farm housewife trading under the names M. Orbert and Orbert 5, promoted through the mails a "simple home treatment" for asthma and hay fever. No medicine was sold, but by sending \$1 the customer received a set of directions for treating the diseases named. First, he was told to "stop eating for three to four days" and live on grapefruit juice and oranges. Next, he was to follow a diet free from proteins and starches and to return to the "juice" program for a few days every two or three weeks. This regimen was to be followed until the customer was "completely relieved of the asthma." After that he was to live on a diet that resembled the vagaries of a "raw food" faddist. At the hearing of this case Mrs. Orbert did not appear or send a representative. Expert medical witnesses testified that Mrs. Orbert's generalized dietary was wholly worthless for effectively treating or permanently relieving either asthma or hay fever, as victims of these disorders would not be desensitized by omitting from their diets the foods proscribed in the Orbert "treatment." On the contrary, the evidence showed that asthmatic patients who followed the rather unvaried Orbert dietary measures might be even more subject to asthma than if they had never taken the "treatment." Accordingly, a fraud order was issued on May 28, 1940 debarring the Orbert scheme from the mails.

Shackleton's Inhaler and Shackleton's Inhaler Compound—These are put out by the Shackleton Inhaler Company of Grand Rapids, Mich., which up to around 1940 was said to be advertising that its inhaler had been "sold for 59 years." From inquiries sent to the Bureau of Investigation from 1918 to 1934 it appeared that the concern was located at Kansas City, Mo., during that period. Since 1935 it seems to have been doing business at Grand Rapids. Investigation by the Post Office Department revealed that the treatment consists of an inhaler and a "filler" which, according to a government chemist, is a water-alcohol solution containing 81.6 per cent of alcohol, 0.34 Gm. per hundred cubic centimeters of methyl salicylate and 0.36 Gm. per hundred cubic centimeters of camphor, with pine tar, eucalyptol and balsamic substances. An expert medical witness testified for the government that though the vapor released from this mixture would give a mild temporary relief from nasal symptoms while being inhaled, its total drug action would be no more than that of a feeble irritant with no germicidal properties, would not dry up the secretions accompanying many respiratory disorders or constrict the mucous membranes of the nasal tract so as to remove any obstruction caused by engorgement thereof. He further testified that upper respiratory disorders are numerous and their causes so varied as to make it impossible to treat all of them effectively with any one stock preparation, such as the Shackleton product. Summed up, the evidence convinced the Post Office solicitor that the business was a scheme to obtain money through the mails by means of false and fraudulent pretenses, representations and promises and accordingly it was debared from the mails by a fraud order issued on Dec. 31, 1940 against the Shackleton Inhaler Company and its officers and agents.

VARIOUS "CURES" BANNED FROM THE MAILS

Abstracts of Some U. S. Post Office Fraud Orders

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

Acme Laboratory—This Kansas City, Kan. concern, also known as Acme Laboratories and run by a George A. Johnson, was charged by the Post Office Department with selling an eye treatment, "D. I. T.," through the mail under false and fraudulent representations. Among these were that the product would afford the quickest possible relief in counteracting infection of the eyes and overcoming swelling, burning and irritation, preserve and prolong normal vision, retard gradual loss of sight due to old age, dispense with the necessity of wearing glasses or the frequent changing of glasses caused by "old age eyes," and cure the disorders known as keratitis and conjunctivitis. The Acme people were further charged with selling by mail a product, "Oroseptol," under the fraudulent representation that it was a "powerful germ killer" and that it would remove the cause of, and restore to a normal healthy state, all soft, sore, bleeding and receding gums, cure pyorrhea and prevent any recurrence of these conditions or the necessity of tooth extraction, or that Oroseptol would overcome "common" sore throat, swollen tonsils, fever sores and other mouth and throat disorders regardless of their cause. At the hearing of this case a government chemist testified that D. I. T. came in two preparations, called "No. 1" and "No. 2," that the first named contained about 0.7 Gm. of boric acid per hundred cubic centimeters of the solution, plus some camphor and traces of acetaminol and epinephrine, and that No. 2 was an acid liquid consisting essentially of 0.25 Gm. of zinc sulfate per hundred cubic centimeters of the solution and a trace of iron. Further, the chemist testified that he had found Oroseptol to be a solution of soap, eucalyptol, pine oil and cinnamon. The government produced expert medical testimony which showed that neither of these treatments would be substantially effective for the conditions played up in the advertising and on Feb. 23, 1940 a fraud order was issued against the names Acme Laboratory and Acme Laboratories and their officers and agents debarring them from the further use of the mails.

Correct Sight Club—This outfit at Allentown, Pa., whose director was a James K. Bowen, sold through the mails some so-called instructions for the elimination of faulty vision. Among the false and fraudulent representations with which the Post Office Department charged it were that its instructions were "personal" to each remitter and would enable him to correct errors of refraction, far sightedness, near sightedness and astigmatism without the use of glasses, that by following these instructions he could restore healthy and natural eyesight and discard his glasses without loss of acuity and bring his "whole body" back to a "younger" stage of life. The instructions were found to consist of six lessons entitled respectively "Relaxation," "Details," "Look and See," "Instantaneous," "Steadiness" and "Shifting." At the hearing of this case the government produced an optical expert who testified that the treatment in question was an ineffective and unscientific one, and Bowen's testimony indicated a conspicuous lack of knowledge about the eye and its disorders. Accordingly, on Oct. 11, 1940 he was debarred from the mails by a fraud order issued against him, the Correct Sight Club and its officers and agents.

Der-Mo-Topic Laboratories—In January 1940 one W. F. Gilroy, president of this concern at Pittsburg, Pa., was ordered to show cause why a fraud order should not be issued against his firm for using the mails in selling "Der Mo Topic Medicated Special Cream" and "Der Mo Topic Psoriasis Cream" under false and fraudulent representations. Among these were that the first named product would remove hemorrhoids, acne, eczema, boils, humors, warts and other cutaneous disorders, besides preventing blemishes and overcoming dandruff, and that the "Psoriasis Cream" would cure psoriasis. In the hearing of this case by the Post Office Department it was revealed that these two products, although sold under different names, are one and the same thing, consisting essentially of about 0.4 per cent of iodine, about 1 per cent of coal tar and a trace of sulfur, all incorporated in a fixed oil base. An expert medical witness for the government testified that the conditions that Der Mo Topic products were represented to correct may be due to many causes which can be effectively treated only by scientific methods and that the Der Mo Topic products therefore would be of little avail. On March 2, 1940 the Post Office issued a fraud order debarbing the Der Mo Topic Laboratories from the use of the mails.

Faultless Laboratories—This Nashville, Tenn., concern was run by a V. A. Tayntor, who also used the name L. B. Taylor in selling through the mails his "Sulpho-Matic" treatment. This he represented as a cure for all forms of rheumatism and a remedy for any case of stomach ulcers, liver, kidney and gallbladder troubles, nervous conditions, blood disorders, tumors, cutaneous diseases, hemorrhoids, fistula and pellagra. When ordered by the Post Office Department to show cause on Aug. 7, 1940 why a fraud order should not be issued against his business, Tayntor sent a letter denying the charges but did not appear at the hearing. The government produced expert medical testimony to show that rheumatism appears in too many forms and results from too many causes to be amenable to any one treatment and that the same could be said of the other diseases for which the Sulpho-Matic was advertised. Government chemists reported that it consisted of six aqueous solutions respectively containing the following (in grams per hundred cubic centimeters): *A 1 Morning*, magnesium sulfate, 35; *B 4 Morning*, magnesium sulfate, 38.3, an oily liquid with an odor of peppermint, 12, and a trace of sulfur, as well as indications of saccharin; *A 2 Noon*, potassium bitartrate, 62, citric acid, 12.48, and anhydrous ferric oxide, 0.09, with wintergreen flavoring; *B 5 Noon*, potassium bitartrate, 55; *A 3 Night*, sulfur, 18.43, and gummy material, 4.54; *B 6 Night*, sulfur 12.73, and gummy material, 4.10. On Oct. 2, 1940 the Post Office issued a fraud order against the names Faultless Laboratories, L. B. Taylor and their officers and agents, debarbing them from further use of the mails.

Marcell Mineral Laboratory—This Pasadena, Calif., concern was known also as The Marcell Mineral Company, The Miracle Mineral Laboratory, The Institute of Sanelogy and Virell, The Nature Man. It also used the name Don Marcell, but the Post Office Department's investigation brought out that the person behind it was an E. F. Marcell. He was reported to be a son of one Marcus B. Marcell, who had founded the business around 1920 in Portland, Ore., and apparently moved it to Pasadena some years later. Old records show that Marcus B. Marcell, who according to a Pasadena newspaper, died in August 1939, had claimed that he was a "naturopathic physician" and also was ordained in Pasadena in 1930 as "a Practitioner of the Spiritual Science Church." In spite of these learnings toward "drugless healing" cults, however, he ran a "patent medicine" business in which he was succeeded by his son, E. F. Marcell, promoting through the mails two nostrums in particular. One of these, "Miracle Mineral No. 1," according to a government chemist, consisted of 35 per cent of sulfates (including those of sodium and potassium), 16.75 per cent of anhydrous ferric oxide and smaller amounts of silica, phosphate, and aluminum and magnesium oxides. The other, "Marcell's San O Min Miracle No. 2 Vaginal Suppository," the chemist reported, contained 16.1 per cent of anhydrous ferric oxide and lesser quantities of aluminum and magnesium oxides, sulfate, silica, sodium, potassium and phosphates. At the hearing of this case an expert medical witness testified for the government that the "No. 1 Miracle" could not purify the blood or benefit the liver, kidneys, skin or nerves as claimed, nor would the epositories remove the cause of female disorders, and that neither of the products was "absolutely harmless." Hence Marcell's representations that the products were found to be a scheme for obtaining money by fraudulent means, and the mails were closed to the concern on Sept. 27, 1940. Incidentally the *Minnesota Medicine* reported in November 1940 that in the previous month Edward F. Marcell of Pasadena was fined \$400 plus cost of \$518 in a

district court in Minnesota for practicing medicine without a license in promoting a "health course" consisting of minerals in capsule form at \$58 per "patient" and was ordered to leave the state and cease advertising in the Minnesota papers.

Reed's Cut Rate Drug Store—This concern at Clarksburg, W. Va., had as proprietors a Lenard Gottlieb and his wife, Sara. They admitted to the Post Office inspectors, however, that they did not manage the store. Nevertheless, the Post Office investigation revealed that the Gottliebs used the store's name to carry on a mail order business in which they sold "Prescription Female Capsules" and auxiliary products for menstrual disorders. The Post Office developed evidence that an inquirer who wrote to the concern for an abortion treatment was advised to buy the "Female Prescription Capsules triple strength, a regular \$10.00 prescription that costs you \$7.50 plus tax." Further, the Post Office reported, the Gottliebs sent this inquirer the "prescription" with adjunct quinine and laxative preparations for accomplishing the purpose in question. The Post Office was convinced that the Gottliebs' business was illegal in its nature and also that it was carried on under the false, assumed and fictitious names of Reed's, Reed's Cut Rate and Reed's Cut Rate Drug Store, and on June 12, 1940 a fraud order was issued to debar the scheme from the mails. On October 22 another government agency, the Federal Trade Commission ordered Lenard and Sara Gottlieb, trading as Reed's Cut Rate Store and Fountain Cut Rate Stores at Clarksburg, W. Va., to cease and desist from certain misrepresentations. Among these were that their Prescription Female Capsules, also designated as "Lady Lydia Female Capsules," are a harmless and effective treatment for delayed menstruation, since the product might cause gastrointestinal disturbances, hemorrhage of the pelvic organs and, in the case of pregnancy, might produce uterine infection and blood poisoning. This case was abstracted in *THE JOURNAL* March 15 1941, page 1178.

Science Laboratories—This concern did business from Erie and Corry, Pa., selling through the mail "Panaroid" and "Bilada Tablets" for hemorrhoids and constipation and "Carthage" for sinus trouble. According to a government chemist's testimony in this case, Panaroid consisted essentially of phenol, tannin, alkaloids from belladonna, stramonium and possibly hyoscyamus with a small amount of epsom salt and ferric oxide. The analysis did not reveal the presence of three other drugs that the promoter claimed were present—quinine sulfate, lead acetate and benzocaine. The Bilada Tablets were reported to consist essentially of carbonates of calcium and sodium with cascara, phenolphthalein and a small amount of bile salts. Carthage, the chemist reported, was composed chiefly of ephedrine hydrochloride, ethyl aminobenzoate and oils of camphor, menthol, cinnamon and pine. As expert medical testimony for the government showed that these treatments were not as effective as represented, a fraud order was issued on March 22, 1940 debarbing the Science Laboratories from further use of the mails.

Washington Health Research Laboratories—Around 1936 one Ben S. Buckmaster was reported to be treating victims of cancer in the Tacoma, Wash., area with a medicine that he alleged was "a miracle cure" and had been handed down to him through four generations in his family. It developed that the stuff then consisted of balsam copaiba, spirit of niter and haafem oil and was made up by a Tacoma druggist. In 1939, it is said, Buckmaster associated himself with a George Baydo in promoting the product as "Buck's Special Mixture." Within six months, however, the two men were said to have disagreed and each proceeded to put out the nostrum separately and to claim his was the original. One Tacoma man is said to have stamped as false a "testimonial" which he claimed Buckmaster pretended to have obtained from him. "Testimonials" also were used by Baydo in his circulars put out under the name Washington Health Research Laboratories. When he began to sell Buck's Special Mixture through the mails his scheme came within the province of the Post Office Department. Finally that agency ordered him to show cause on Sept. 18, 1940 why a fraud order should not be issued against his business, but instead of attending the hearing he merely sent a written reply denying the charges. The Post Office showed that Baydo had sold his "cure" not only for cancer but also for ulcers, tumors, tuberculosis, rheumatism and some more things. In one case it was shown that Baydo had even represented it as a cure for syphilis and gonorrhea. A government chemist testified that the mixture consisted essentially of an alcoholic, oily fluid containing ethyl nitrite, sulfur and copra. As expert medical testimony showed that such a mixture would not cure any of the diseases enumerated, a fraud order was issued on Oct. 2, 1940 closing the mails to the Washington Health Research Laboratories, George Baydo and their officers and agents.

Z-Rin Products Co.—This concern at South Bend, Ind., had as its president and general manager a John Zrinz and sold through the mails "Zinex Special Ointment for overcoming 'pile conditions'" and "Z Rin" which was represented to cure the "agonizing" pains of various forms of rheumatism. At the hearing of the case a government chemist testified that the first named product was essentially a mixture of mercury and nitric acid combined in a weak or diluted ointment of mercuric nitrate and that Z Rin was chiefly composed of salicylic acid, potassium acetate and common sugar, with small amounts of plant extracts including caliche and cinchona. Since expert medical testimony was produced showing that these nostrums would not cure the conditions for which they were advertised, the Post Office on Sept. 13, 1940 issued a fraud order against the names "Z Rin Products" and "Z Rin Products Co." and John Zrinz.

Correspondence

EXCRETION OF SILVER IN URINE

To the Editor:—We have just read the communication by Dr. Victor Jacobson in *THE JOURNAL* of Nov. 1, 1941, page 1557. It may be of interest that one of our unpublished observations confirm his point of view that silver is not excreted in the urine. Some years ago we studied a case of obvious argyria, and we tried by the technics which we had used in cases of lead poisoning to withdraw the silver from its depots in the body. In spite of a prolonged investigation, with fairly heavy deleading treatment, no measurable amount of silver was ever found in the urine. From this we decided that lead and silver differed greatly in their metabolic responses in the body.

PSYCHOTHERAPY

To the Editor:—Dr. Andrew D. Hart Jr.'s comment in *THE JOURNAL*, Dec. 6, 1941 anent Dr. Roy Grinker's communication of October 18 contains many pertinent and justifiable criticisms of the attitude of the medical profession toward the neurotic patient.

Dr. Hart's apt quotation "It is the great error of our day in the treatment of the human body that physicians separate the soul from the body" is only partially true, for this quotation implies that the medical profession generally does not recognize or treat the "soul." As a matter of fact the "soul" is recognized and treated by every practicing physician every day whether he does it consciously or unconsciously. A good example of conscious psychotherapy is the immemorial use of the placebo. The adroit use of personality, or bedside manner, is an unconscious use of psychotherapy.

It is perhaps the undisciplined use of psychotherapy, whether conscious or unconscious, for which the average practitioner should be chiefly criticized. Add to this the impatient criticism of the "neurotic" in the unconscious of the physician and Dr. Hart's criticisms become fully justified.

How many of us are aware of the fact that the "bedside manner" produces a potent and at times inimical, at times beneficial, force which the psychologists term "transference"? Beneficially used, the transference is a therapeutic phenomenon of considerable value of which the average practitioner not primarily trained in the technic of psychotherapy is now almost completely deprived. In days gone by, in the days of the family doctor, there existed a much more perfect understanding between physician and patient. In those days the patient turned to his medical counselor for advice pertaining not only to medicine but also to his marital and family difficulties. He "exposed his soul" and received balm for it. Undoubtedly his body benefited thereby.

We all recognize the existence of psychologic components in our cases, but in most instances we do not analyze or identify them unless we are pursuing a clinical experiment. Here again, by the use of controls, we often give tacit acknowledgment to the existence of psychologic components.

It is our duty as physicians, if not inclined to devote the time or effort necessary for evaluating or analyzing the psychologic components in our patients' complaints, to refer them to properly qualified psychotherapists who should act as the catalyst welding together the busy doctor and his patient. Undoubtedly one difficulty heretofore has been the agnostic attitude of the profession generally. If the average medical practitioner is asked "What about psychotherapy?" he probably will answer "Well, there is something to it." That is a step forward. The nega-

tivistic skepticism of twenty years ago has been replaced by tolerant agnosticism. This is an indication of healthy progress in view of the fact that the scientific history of the last three hundred years has conditioned the medical profession against intangibles. It was only after Charcot, Freud and Pavlov that the psychologic factors were again recognized in health and disease. It is now a well accepted principle that many manifestations of psychogenic disorder are mediated through the various physiologic systems of the body. There is good evidence that thought itself has a physiologic basis. Psychotherapy today is not a specific and cannot control the psychologic processes by definite formulas. At best psychotherapy is still in its swaddling clothes. Whether it will develop into a full fledged science before medical therapy can take its place cannot be said.

It is still important that psychogenic disorders be not confused with organic pathologic conditions. A systematic psychiatric examination should be an integral part of every diagnostic process. This would often prevent many expensive and time consuming diagnostic laboratory procedures. Early discovery and correction of psychogenic pathologic conditions would prevent the creation of that tragic personality who goes from doctor to doctor becoming more and more discouraged, gaining a deeper sense of frustration and a more definite series of psychosomatic symptoms.

Obviously then, and despite his conditioning against intangible etiologic factors, it is the duty of the doctor of medicine to become more sympathetic toward psychotherapy as an adjunct rather than a separate entity both for his own and his patients' sake.

HYMAN MILLER, M.D.,

HAROLD F. FREY,

Los Angeles.

ADDRESS OF OLIVER WENDELL HOLMES TO THE MEDICAL STUDENTS—1861

To the Editor:—Eighty years ago on Nov. 22, 1861 Oliver Wendell Holmes, Parkman professor of anatomy and physiology at Harvard University, addressed the medical class and ended his introductory lecture, published at the request of the class, with the following stirring words:

"It is time to bring these crowded remarks to a close. The day has been when at the beginning of a course of lectures I should have thought it fitting to exhort you to diligence and entire devotion to your tasks as students. It is not so now. The young man who has not heard the clarion voices of honor and of duty now sounding throughout the land will heed no word of mine. In the camp or the city, in the field or the hospital, under sheltering roof or half protecting canvas or open sky, shedding our own blood or stanching that of our wounded defenders, students or teachers—whatever our calling and our ability, we belong, not to ourselves, but to our imperiled country, whose danger is our calamity, whose ruin would be our enslavement, whose rescue shall be our earthly salvation!

"You cannot all follow the armies of your country to the field. But remember that he who labors for the general good at home is an ununiformed soldier in the same holy cause with those who bear arms or minister at the side of the ambulance and in the camp hospital. Larrey claimed no precedence of Dupuytren, nor Guthrie of Sir Astley Cooper. As for the nobleness of the task for which you are preparing yourselves, I do not know that I can speak of it more strongly in prose than I did in the peaceful times before these days of trial, in the form of verse, and I will so far trespass on your time and patience as to close this lecture by reading you [The Two Armies, an original poem]."

The poem is rather long to reprint, but the inspiration of these words of the beloved Holmes should help all physicians in the fight to safeguard our heritage of individual and political freedom. The call to arms today is more urgent than it was even in 1861.

B. S. OPPENHEIMER, M.D., New York.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE
CHICAGO, Feb. 16-17, 1942. Council on Medical Education and Hospitals, Sec., Dr. William D. Cutter, 535 North Dearborn Street, Chicago.

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL*, January 17, page 249.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Feb. 9-11. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral. Part II.* Atlantic City, June 6-7. Final date for filing application is March 7. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* St. Paul, April, in advance of the meeting of the American College of Physicians, and Philadelphia, June, in advance of the meeting of the American Medical Association. Applications should be on file 6 weeks in advance of the date of oral examination. *Written.* Oct. 19. Final date for filing application is Sept. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: New York, June. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Oral. Part II. Groups A and B* Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral.* Baltimore, June 6 and Philadelphia, June 8. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral and Written. All Groups.* Philadelphia, June, preceding the meeting of the American Medical Association. Final date for filing application is March 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PATHOLOGY: St. Louis, March 30-31. Final date for filing application is Jan. 30. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: *Written.* Locally, February 14. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: *Oral.* Boston, May 15-16. Final date for filing application is March 1. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: *Oral. All Groups.* Atlantic City, June 4. Final date for filing application is April 1. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written. Part I.* Various centers, March 2. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

New York Endorsement Report

The New York State Board of Medical Examiners reports 87 physicians licensed to practice medicine by endorsement from June 19 through September 9. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Yale University School of Medicine.....	(1939) N. B. M. Ex.

California July Report

The Board of Medical Examiners of the State of California reports the written examination for medical licensure held at San Francisco, July 1-3, 1941. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and fifty-four candidates were examined, 149 of whom passed and 5 failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
College of Medical Evangelists.....	(1940), (1941, 5)		6

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Abortion: Natureopath Convicted of Attempting to Procure Miscarriage.—The complainant, a married woman, was advised on June 3, 1940 by a physician that she was pregnant. About three weeks later she consulted the defendant, a licensed natureopath, concerning her condition, informing him that she had missed her last period and that she suspected pregnancy. The natureopath examined her. Subsequently she made six other visits to his office, being accompanied twice by her husband. On the suggestion of the natureopath, the husband purchased a catheter, which was given to the wife. Following the next visit to the natureopath the wife, apparently on the natureopath's suggestion, directed her husband to purchase another catheter. On at least one of the visits the natureopath inserted in her body one of the catheters, cutting off part of it, and told her to go home and go to bed. As a result of the defendant's treatment a miscarriage was produced. The natureopath was charged with committing "the crime of attempt to procure a miscarriage." At the trial the natureopath testified in detail as to what his examination of the complainant disclosed and the history which she gave him, including complaint of pain and spasm, and stated that on the information so obtained his diagnosis was that she was not pregnant but was suffering from metritis and stenosis of the womb with a consequent uterine congestion, which had interrupted her regular periods. He inserted the catheter, he testified, in the cervix to dilate it to relieve the pain and with no intention of performing an abortion. The natureopath was convicted and appealed to the Supreme Court of Errors of Connecticut.

The determinative question, said the Supreme Court of Errors, is whether or not the trial court was warranted on all the evidence in finding beyond a reasonable doubt that the natureopath had the guilty intent essential to conviction of the crime of attempting to procure a miscarriage. In urging that the trial court was not so warranted, the natureopath invoked the principle that, in determining whether evidence establishes guilt beyond a reasonable doubt, any conclusion reasonably to be drawn from the evidence consistent with the innocence of the accused must prevail. The defendant contended that the following facts, which appeared from the evidence, supported his claim as to the absence of a guilty intent on his part: entries under the date of the first visit of the complainant to his office of her name, of his diagnosis and of her payments, made in his desk book which he kept in his office with no attempt at concealment; the retention in his office likewise of the portion of the catheter not used; and his instructions to the complainant after treating her that in the event she became sick she should call a physician to take care of her, notwithstanding he knew that it would be the duty of the physician to report the situation if an abortion was involved. The natureopath also claimed that on the history given by the complainant to him and the physical condition revealed by his examination, the diagnosis which he made of stenosis of the cervix and excluding pregnancy was a possible one, that dilation of the cervix to relieve the pain is proper treatment of stenosis, and that the defendant, being but a natureopath, cannot be held to the same standards of skill and expert knowledge as a physician. Assuming, said the Supreme Court of Errors, that the purport of the evidence relied on should be construed to be as contended by the natureopath for the purpose of applying the principle in question, his claim cannot prevail because of other evidence in the record that the defendant did have guilty intent. The complainant made six visits to the natureopath's office and he was paid \$50 in four payments during the course of the treatment. The natureopath himself testified that he knew what the result of inserting the catheter would be if the complainant was pregnant and he stated, apparently to the officer who had arrested him, that on the 27th and 28th of June the complainant "came again and I cleaned the womb and she did not come around. . . ." This evidence, fortified by the testimony of the physician who had

made the original diagnosis of pregnancy that in his opinion the sole purpose of inserting a catheter in a woman's cervix is to produce an abortion, makes clear that the trial court could have properly concluded that the contentions of the natureopath went, at most, not further than to raise a possible, as distinguished from a reasonable, doubt as to his guilty intent. As such, it cannot avail the natureopath. The judgment of conviction was accordingly affirmed.—*State v. Santoro, 22 A. (2d) 793 (Conn., 1941).*

Malpractice: Qualifications of Expert Medical Witness; Admissibility of Photograph of Abdominal Scar.—The patient underwent an appendectomy in a private hospital conducted by the defendant physician. Bad results followed and it was subsequently necessary for the patient to submit to another operation for the repair of a ventral hernia, caused, contended the plaintiffs, by the defendant's negligence in making too long an incision for the appendectomy and in failing properly to suture the wound afterward. Accordingly the plaintiffs, the patient and her husband, each sued the defendant physician for malpractice. The two suits were consolidated for trial and, from judgments for the plaintiffs, the defendant appealed to the Supreme Court of Michigan.

The defendant contended that a photograph of the scar on the patient's abdomen had been improperly received in evidence. The evidence showed that the photograph was made after the trial was in progress and the testimony showed that the incision made by the defendant was lengthened by the second operation to repair the hernia, which was performed more than two years after the appendectomy. The plaintiffs claimed that the photograph was admissible because there was a question as to the length of the original incision, and that it was at least admissible to challenge on this point the credibility of the defendant's medical witnesses. The Supreme Court held that the admissibility in evidence of a photograph is largely within the discretion of the trial judge. In *Davis v. City of Adrian*, 147 Mich. 300, 110 N. W. 1084, the photograph of an ulcerated sore was held properly admitted when the jury had been instructed as to the consideration to be given to the accompanying testimony. In the present case, the trial judge stated, in the presence of the jury, that the picture was not admissible to show the length of the incision at the time the defendant operated and the jury was aware that the photograph had been taken after a second operation and during the trial of the case. The Supreme Court held that the rights of the defendant had been amply safeguarded by these statements of the trial court and concluded that the admission of the photograph was not an abuse of discretion.

The defendant relied mainly, however, on the contention that the plaintiffs had not produced any competent expert evidence of malpractice because the plaintiffs' only medical expert was not adequately qualified to express an opinion; that witness was permitted to testify as to the practice of surgery in Detroit and similar communities. The evidence showed that the witness had graduated from a medical school in Canada and was admitted to practice medicine and surgery in Michigan in 1902. Between 1902 and 1929 he practiced medicine, for periods of from a few months to a few years, in the upper peninsula of Michigan, in Chicago, in Perth, N. D., in British East Africa, in Alliance, Neb., in Mexico, in Blue Hill, Ainsworth, Gordon, Sidney and Potter, Neb., and other towns in Nebraska, Colorado and Louisiana. In 1929 he returned to Michigan and, after living in several communities, finally settled in Ferndale in 1932. This witness testified that he had never attended or witnessed any operation whatever in the city of Detroit or its vicinity, that he was acquainted with only one physician there, a physician with whom he once had a casual conversation, that "he never practiced, except as a consultant to some attorneys" and that he had not performed an operation for ten or twelve years. The question of competency, said the Supreme Court, is for the trial judge to determine, and he must decide within the limits of a fair discretion whether the experience of the witness had been such as to make his opinion of any value. Opinion evidence, the Court continued, may not be given by one who has no knowledge or experience. In ruling on the defendant's motion for a directed verdict, the trial judge seemed satisfied that the witness had no knowledge of the

medical standards in Detroit and similar communities and that this would disqualify him as an expert, but he nevertheless concluded that the issue concerned the weight rather than the admissibility of the testimony. The Supreme Court concluded otherwise, however, and held that the trial court erred in refusing either to strike the testimony of the witness or to instruct the jury that the opinion expressed by him was entitled to little or no weight. Accordingly the judgments for the plaintiffs were set aside and the cases were remanded to the trial court for a new trial.—*Perri v. Tassie (two cases)*, 292 N. W. 370 (Mich., 1940).

Medical Practice Acts: Use of Preposterous Mechanical Device for the Alleged Treatment of Human Ailments as Gross Immorality Justifying Revocation of License to Practice.—The appellant, Crum, after attending for one year the College of Drugless Physicians in Indianapolis, which the Supreme Court of Indiana in the reported case characterized as a diploma mill, graduated therefrom with the degree of doctor of naturopathy, doctor of electrotherapeutics, doctor of chiropractic and doctor of herbal materia medica. He was licensed without examination in Indiana under the so-called grandfather clause of the Indiana Medical Practice Act to practice chiropractic, naturopathy and electrotherapeutics. He established an office in Indianapolis and from time to time used numerous kinds of mechanical devices in the practice of the several "professions" he was licensed to practice in Indiana. In 1936 he obtained a United States patent on a mechanical contrivance, which he dubbed an "etherator" or "co-etherator," for the diagnosis and treatment of various human ailments. This machine was a small wood box with a number of holes in the front over which various colors of thin paper were pasted. On the inside was an ordinary light bulb with a cord for making contact with electricity. The bulb could be moved about so that light would penetrate the various paper-covered holes. The box also contained a quantity of disconnected wire and a glass tube filled with ordinary hydrant water. There was a pedal and a dial on the outside of the box, neither of which had any connection with the interior. Crum, in using this machine, would have the gullible patient moisten a slip of paper with saliva and deposit it through a slot on the top of the box, or Crum would make similar use of the patient's photograph or a specimen of his handwriting. After this was done, Crum would rub the pedal with his thumb and talk to the machine, repeating the popular names of diseases and organs of the body. By this procedure Crum claimed to be able to treat, relieve and cure cancer, blindness, arthritis, nervous disorders, hemorrhoids, abscesses, kidney ailments, stomach disorders, leakage of the heart, skin ailments, ovarian trouble, varicose veins and tumors. He also claimed that by so using the machine he could lengthen or shorten a patient's legs, cause amputated fingers to grow back into place and fill cavities in teeth by restoring them to their natural condition. According to his claim it was not even necessary for patients to be present or visit his office but that with the machine he could broadcast treatments to them wherever they might be located. The machine, he also claimed, enabled him to "administer 'financial treatments' by means of which money could be put into the hands of his patients"; and that the machine "could fertilize fields to a distance of 70 miles," kill dandelions and "treat golf greens . . . so that clover would turn brown and dry up and give the grass a chance to grow."

The state board of medical registration and examination, acting on a complaint filed with it that the claims made by Crum in connection with the use of this machine constituted "gross immorality," which under the medical practice act of Indiana was a cause for the revocation of a license to practice medicine or healing, revoked his various licenses to practice in Indiana. Crum appealed to the circuit court, Marion County, which found him guilty as charged, and he then appealed to the Supreme Court of Indiana.

Crum first contended that the allegations in the complaint filed with the state board of medical registration and examination do not amount to a charge of gross immorality. He reasoned that since he was licensed to practice chiropractic, naturopathy and electrotherapy, his right to do the things charged in the complaint was "recognized and legalized." It

is not necessary, said the Supreme Court, to define what properly constitutes the practice of chiropractic, naturopathy or electrotherapy or to enter into any extended discussion as to what conduct is forbidden by the term "gross immorality" as used in the Indiana medical practice act. It is enough to say that this Court will not judicially presume that the Indiana legislature intended to authorize a course of conduct so reprehensible and revolting as to shock the sensibilities of reasonable men. On the contrary, it must be assumed that in providing for licenses to practice possessed by Crum, the legislature intended that the methods employed in practicing under those licenses should bear some rational relationship to the alleviation of human ill. In the opinion of the Court, the allegations of the complaint sufficiently charged gross immorality.

Crum next contended that, since a section of the Indiana medical practice act forbids the board to discriminate against any school or system of medicine, to brand his practices as described in the complaint as immoral would require that his conduct be measured by the standards exacted by other schools of medicine and that this in turn would call for mere expressions of opinion rather than facts as to the curative value of his so-called treatments. The issues, he argued, raised by the charges are therefore beyond the inquisitorial purview of the board and without the reviewing jurisdiction of the courts. The complaint filed with the board, said the Supreme Court, discloses no such fundamental controversy between the concepts of hostile schools of the medical and healing sciences. The charge was, in effect, that Crum used a device of no possible therapeutic value under any recognized system of treatment and that he knowingly made false and fraudulent claims with respect to it for his own profit and to the injury of others. No licensee of this state may rightfully claim the privilege so to practice. The fact that in the enforcement of the law the administrative agency and the courts may sometimes find it proper or convenient to consider the opinions of skilled and competent experts in determining the virtue of such practices does no violence to due process or vested rights. The complaint was sufficient.

The very mention of the extravagant claims made by Crum, continued the Court, is sufficient to suggest their untruthfulness and brand them as designedly fraudulent. His case is not helped by the fact that he produced numerous witnesses at the trial who voluntarily testified as to "miraculous" cures that had been brought about by the use of his machine. "Hope springs eternal in the human breast" and it is not uncommon for persons who are afflicted with dreadful diseases to be misled and beguiled into believing that they have been helped by quacks and charlatans. It is reasonable to suppose that by the enactment of the medical practice act it was the deliberate purpose and intention of the legislature to protect such unfortunate people from their own credulity. The evidence, in the opinion of the Supreme Court, was sufficient to justify the trial court in finding that Crum was guilty of gross immorality and that he was utterly unfit to be licensed by the state to treat human ailments. The action of the board in revoking his license was in effect affirmed.—*Crum v. State Board of Medical Registration and Examination*, 37 N. E. (2d) 65 (Ind., 1941).

Society Proceedings

COMING MEETINGS

Annual Congress on Medical Education and Licensure, Chicago, Feb. 16-17. Dr. William D. Cutter, 535 North Dearborn St., Chicago, Secretary.

American Orthopsychiatric Association, Detroit, Feb. 19-21. Dr. Norvick C. LaMar, 149 East 73d St., New York, Secretary.
Central Surgical Association, Chicago, Feb. 27-28. Dr. George M. Curtis, Ohio State University, Columbus, Ohio, Secretary.
Mid-South Post Graduate Medical Assembly, Memphis, Tenn., Feb. 10-11. Dr. Arthur F. Cooper, 165 Madison Ave., Memphis, Tenn., Secretary.
Pacific Coast Surgical Association, San Francisco and Del Norte, Calif., Feb. 17-20. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.
Society of Surgeons of New Jersey, Trenton, Jan. 23. Dr. Walter I. Mount, 21 Plymouth St., Montclair, Secretary.

Current Medical Literature

AMERICAN

The Association Library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Bacteremia Caused by *Staphylococcus Aureus*.—Skinner and Keefer studied 122 cases of bacteremia caused by *Staphylococcus aureus*. Only 22 patients recovered. Several conditions are necessary for recovery. The blood stream must be cleared of bacteria and the infection localized and drained or allowed to resolve spontaneously. However, some patients die from the effects of infection even though their blood streams are cleared of organisms, and in them the soluble products (toxins) of the staphylococci are probably important. Presumably, the toxins in the patients who recover are neutralized and the organisms destroyed. Burnet showed experimentally that hemolytic, dermatonecrotic and lethal toxins were formed *in vivo* and that immunization did not protect animals against experimental infection. The evidence, though incomplete, indicates that man recovers only if the blood is cleared of organisms, the infection localized and the toxic effects of the infection neutralized.

Tests for Syphilis.—Mohr and his colleagues present cases which show that apparently normal, nonsyphilitic persons may temporarily or permanently possess a reagin or a reagin-like substance in the blood which reacts positively in standard serodiagnostic tests for syphilis. The biologically false positive reactions of the persons concerned were verified in different laboratories and by other methods than the supersensitive flocculation tests. Despite these false reactions, the authors suggest that it may be that the antibody present in syphilitic serum is strictly specific and that normal serum contains other substances with qualitatively similar effects on the lipoidal suspensions used as an "antigen." Thus, a normal serum may be capable of causing the aggregation of these lipoidal suspensions to cause clumping indistinguishable from that caused by syphilitic serum, even though the mechanism of the aggregation is dissimilar.

Marginal Malnutrition.—Robinson and his associates selected 5 patients whose condition was diagnosed as diabetes mellitus by the criteria of Extton and Rose; Gould, Altschuler and Mellen, and Matthews, Magath, Berkson and Gage. The authors attempted to show that although the 5 patients had

definite diabetic curves the curves were probably indicative of malnutrition. With proper treatment the curves have returned to normal and the patients have a normal carbohydrate metabolism without treatment. The patients had various types of mental disorders. Such patients, the authors say, are excellent material for studies in malnutrition, especially of the marginal type, because their habits and symptoms lead to this state, and these physiologic abnormalities will develop in any malnourished person. They believe that the dextrose tolerance test should be of value to the general practitioner as both in psychiatric and in general practice there are many patients with a history of easy fatigue and other symptoms of malnutrition in whose treatment the determination of the state of nutrition is an important factor. It was for these patients that the authors found the test and its interpretation of great value. When they first began to determine the dextrose tolerance curve routinely, they observed that the most disturbed curve occurred in patients with the most profound malnutrition. No other common denominator was demonstrable. This interpretation was confirmed by the return of the curve to normal after malnutrition was corrected. The psychosis had no effect on the curve. Some patients had a psychiatric recovery without the metabolism returning to normal, while in others the curve returned to normal while the psychosis was still as active as it had been at the time of admission. The authors consider dextrose tolerance a satisfactory test for the state of nutrition as well as for diabetes mellitus, and they believe that a diagnosis of diabetes mellitus should not be made for any patient with an abnormal dextrose tolerance curve until a full diet has been given for an appropriate period and the dextrose tolerance curve has not returned to normal.

Estrogens and Anemia.—Tyslowitz and Dingemanse state that anemia develops in healthy dogs after treatment with large doses of estrogenic substances (theelin, estradiol benzoate and diethylstilbestrol). Androgenic substances (testosterone or its propionate) do not produce anemia even after months of treatment. The most striking effect was a fall in the erythrocytes, reticulocytes and thrombocytes. Granulocytopenia often occurred after an initial leukocytosis with a shift to the left. The anemia was hyperchromic at first and later it became normochromic or hypochromic. The total quantity of estrogen tolerated depended on the daily dose; a dose of 5 mg. daily for sixteen to forty days was fatal for a dog of 10 Kg. (22 pounds), while the administration of 1 mg. daily for as long as nine months appeared harmless. The simultaneous administration of estrogens and liver extracts did not prevent the anemia. The course of the anemia, the differential leukocyte count and the frequent occurrence of granulocytopenia point to a primary injury to the bone marrow.

Renal Blood Flow in Hypertension.—Chasis and Redish used the clearance method to measure the renal blood flow of the separate kidneys of 21 patients with essential hypertension. The results indicate that the destruction of tubular tissue progresses equally on the two sides in hypertensive disease and that the functional disturbance in the blood flow and the filtration rate is shared equally by the two kidneys. There was no indication of unilateral renal ischemia. The study refutes the widely accepted premise that unilateral renal disease in man is the primary cause of arterial hypertension.

Prophylactic Influenza Vaccination.—Brown and his collaborators present the data of an epidemic of influenza A which occurred in San Francisco in November and December 1940 and January 1941. They present also the results of prophylactic inoculation against the disease influenza A. Antibody studies

indicated that influenza A was the causative agent in 75 per cent of the many patients so studied. Two hundred and seventy-three of 1,213 persons were given subcutaneous inoculations of the complex influenza A vaccine of Horsfall and Lennette. The group studied consists of the population of the University of California Medical Center in San Francisco. The injections were given on November 26 and 28 and December 3. The epidemic had been in progress a few days before the first inoculations were carried out. There were no significant reactions to the injections. A febrile disease resembling influenza occurred in 235 of the 940 control subjects, an incidence of 25 per cent, as compared to 36 among the 273 inoculated persons, an incidence of 13 per cent. The incidence of influenza was much higher (43 per cent) in the hospital control group (nurses, resident physicians and technicians) than in the general control group, either because of better observation or because of greater exposure. Only cases of established influenza A were considered. Of the inoculated persons who subsequently had influenza, only 4 acquired it more than ten days (eleven, twelve, twenty-three and thirty-nine) after inoculation. The occurrence in 2 of these shows clearly that vaccination did not afford certain protection. The incidence of influenza A in the epidemic reached its peak during the ten days after vaccination, and it subsided rapidly during the time when vaccination might be expected to become effective. However, the difference in incidence in the two groups is striking and may be due to a protective effect of vaccination which began sooner after inoculation than is usually considered likely.

Circulatory Failure in Infections.—Ebert and Stead studied the effect of the following procedures on the circulatory failure of 8 patients with acute infections (1 with lobar pneumonia, 4 with lobar pneumonia and bacteremia, 1 with streptococcal septicemia, 1 with staphylococcal septicemia and 1 with bronchopneumonia): elevation of the foot of the bed, transfusion of whole blood or plasma and infusion of a 10 per cent solution of dextrose in saline. None of these measures produced any improvement in the circulation. Improvement in the circulation occurred only after the infection had been controlled. Data suggest that in circulatory failure in acute infections the entire cardiovascular system is apparently damaged by the infection.

"Reversible" and "Irreversible" Atelectasis.—Jacinto and Lahoz state that serial teleroentgenograms and anteroposterior or lateral tomographic exposures of the chest made it possible to diagnose atelectatic pulmonary consolidation in 4 living subjects. The tomographic exposures were especially useful in differentiating between pleural and pulmonary opacities, which at times appeared the same in the conventional roentgenogram of the chest. The atelectatic pulmonary consolidation in 3 patients was tuberculous, and in 1 it was nontuberculous. In the last patient the presence of the bronchial obstruction was verified by a bronchogram made with the aid of iodized oil and by bronchoscopic examination. Massive pulmonary atelectasis is classified as "reversible" and "irreversible," depending on whether pulmonary reaeration is or is not possible. Massive pulmonary atelectasis in Filipinos, the author says, is not as rare as is currently believed.

Spontaneous Pneumoperitoneum.—Rigler describes a new roentgen sign of pneumoperitoneum. It is manifested in the ordinary scout roentgenogram of the abdomen made with the patient in the supine position. Chiefly the sign consists in the ability to visualize, on the film, the outer as well as the inner wall of the intestine. It appears to occur only when relatively large quantities of gas and some fluid have entered the peritoneal cavity. The sign is not a rare one, as it was present in 5 cases of acute perforation of the colon in which reasonably satisfactory roentgenograms were obtained with the patient in the supine position. Careful examination of the routine roentgenogram may reveal the supervention of perforation and peritonitis, and thus the first evidence that more radical treatment is required will be had.

Sulfanilylguanidine for Flexner Dysentery.—Anderson and Cruickshank assessed the value of sulfanilylguanidine for Flexner dysentery by giving the drug to alternate patients in a hospital for patients with mental disorders in which a severe epidemic began in December 1940 and continued, with intermissions, until June 1941. There were 130 adult patients, but as only those who had blood and mucus in their stools or for whom there was bacteriologic proof that they were suffering from Flexner dysentery were accepted for analysis the number was reduced to 96, of whom 41 were treated with the drug and 55 were untreated controls. The drug, in powder form, was suspended in water or milk. The amount was 9 Gm., given in three doses for two days and followed by the giving of 4 Gm. a day in two doses. If the diarrhea was not controlled within four days the maintenance dose of 4 Gm. a day was continued for one week. A liberal intake of fluid was insisted on during the period of chemotherapy. In a typical case of severe dysentery the patient's condition improved in twenty-four hours after his receiving the drug, and by the third day the patient was feeling much better, the toxic symptoms had disappeared and the appetite had returned. Bowel movements became much less frequent within two days, though blood and mucus often persisted for three to four days. Convalescence was much shorter than in the untreated patient. Treatment with the drug in the acute stage of the infection apparently prevented the convalescent carrier state, which was present in about half of the untreated patients. The use of desoxycholate-citrate agar as a culture medium resulted in the isolation of *Bacterium dysenteriae* (Flexner) from a high proportion of typical and atypical infections. Its superiority over MacConkey's medium was most noticeable in that the pathogen was isolated during convalescence. The combination of sulfanilylguanidine and the culture medium, which readily detects mild infections and convalescent carriers, may be instrumental in eliminating dysentery from hospitals for persons with mental disease. The drug could be used, particularly in wartime, for the control of dysentery.

A Selective Medium for *Bacterium Dysenteriae*.—Wilson and Blair found that lactose nutrient agar containing, per hundred cubic centimeters, 0.5 cc. of a 1 per cent alcoholic solution of rosolic acid, 0.5 cc. of a 1 per cent solution of potassium tellurite and 1 cc. of a 4 per cent solution of iron alum provided a medium on which Flexner's *Bact. dysenteriae* grew profusely, whereas the growth of most strains of *Escherichia coli* and *Bacillus laetis aerogenes* was inhibited. The growth of *Salmonella* food poisoning organisms, typhoid and paratyphoid bacilli, Sonne's bacillus and cholera vibrios was suppressed.

A New Sulfanilamide Derivative.—Mutch used sulfonamide ethyl-alpha-sulfonate for the treatment of 130 patients with various acute infections. The new drug is freely soluble in water, it is almost tasteless and infants and patients in coma or those who are vomiting or have diarrhea can be easily treated by giving the drug by mouth, nasal tube, rectal tube or intravenous drip. General malaise was slight, and pallor, nausea and vomiting never occurred. Cyanosis was common, but it never caused distress or required the discontinuance of therapy. Routine blood counts were made but granulocytopenia or simple leukopenia was not encountered. Minor degrees of anemia were observed, but not with greater frequency or

severity than is usual after a severe infective illness. A simple erythematous rash developed in a child after a week of treatment. The rash might possibly have been prevented by a freer use of alkalis. In general there were no serious complications, and the usual symptoms which distress without endangering the patient when sulfapyridine is used were absent. As the expected recovery rate in the disorders treated is reasonably high even with nonspecific therapy a datum line from which to judge the success of the new drug is difficult, and therefore the author stresses the results obtained in 34 cases of acute epidemic cerebrospinal meningitis. Three of the patients died, but there were no deaths among those who were seen during the first week of illness and who remained free of serious secondary infections of the viscera. The temperature of some patients was normal after thirty-six hours of treatment. The recovery of some patients was complete in as little as two and a half weeks.

Size and Visibility of Filtrable Bodies.—Coles believes that all the filtrable virus bodies, including that of foot and mouth disease and infantile paralysis, are easily within the range of the ordinary microscope when it is used correctly. Ultramicroscopic methods have so far added little to the knowledge of viruses. He has used Nelson's method of measuring by extinction for many years. He has found a Leitz 1/10a fluorite objective fitted with an iris diaphragm graduated in numerical apertures, immediately behind the back lens, remarkably accurate. Briefly, the method is to bring the object just to the point of invisibility by reducing the numerical aperture, and then the correction for antipoint will be the measure of the object. The minimal visibility of any objective can be determined by the following calculation: For white light of 45,300 waves per inch (2.4 cm.) 1,041 is divided by the numerical aperture; for green light of 50,000 waves per inch 0.942 is divided by the numerical aperture of the objective.

*Pathologic Changes in Bones Due to Peanut Feeding. I. Kohno.—p. 748.

Osteopathy Due to Peanut Feeding.—Kohno fed a litter of 8 rabbits and 2 control rabbits with raw ground peanuts daily in amounts varying from 1 to 5 Gm. per kilogram of body weight, the experimental feeding starting as soon as the young animals were weaned. Six animals died of gastrointestinal disturbances at intervals ranging from twenty-three to fifty-three days, only 3 animals surviving sixty-two days, at which time they were killed. Histologic examination of the bones in these animals revealed severe hyperplasia of the intermediary cartilage zones, abnormal prolongation of the cartilage matrix and diminution of the total length of the bones. The cortex of the tubular bones was greatly reduced in thickness and of a spongy consistency, with the external and internal periosteal tissues greatly thickened. The bone marrow generally showed fibrotic changes which produced a shortening of the bones corresponding with the degree of the osteopathy. These changes of bone resembled in part those seen in alimentary osteopathy produced by alkalosis; but they more closely resembled the changes of alimentary osteopathy encountered in acidosis. These observations led the authors to conclude that together these changes represent a new distinct osteopathy due to peanut feeding.

Geneeskundig Tijdschr. v. Nederl.-Indië, Batavia
81:1629-1676 (Aug. 5) 1941

*Alarming Frequency of Venereal Diseases and Necessity of Social Hygienic Measures to Reduce it in Netherland East Indies. R. D. G. P. Simons.—p. 1630.

*Skin Disorders Caused by Sunlight. P. H. J. Lampe.—p. 1639.
*Lead Encephalopathy in a Chinese Infant. Loë Ping Kian.—p. 1667.
*Simple Method for Blood Transfusion. H. Oosterveen.—p. 1673.

Venereal Diseases in East Indies.—Simons estimates that in Java (and Madoera) from 10 to 15 per cent of the population of the age level between 18 and 50 are infected with venereal disease. He thinks that the high frequency is chiefly due to the fact that 50 per cent of the patients with venereal disease undergo no treatment at all. The country is overrun with quackery. "Wonder doctors" publish the slogan that "native

ailments" must be treated with native herbs. Only a few hospitals perform serologic examinations during pregnancy. There is no follow-up study and no partner treatment. Brothels flourish in the cities. Investigation of the houses of prostitution only makes the prostitutes flee to their villages. Lack of social hygienic methods and lack of proper instruction have the effect that 75 per cent of the patients who submit to first treatment do not continue until complete recovery.

Skin Disorders Caused by Sunlight.—Lampe applies the term phototrauma to lesions produced by excessive irradiation on a skin of normal sensitivity. Examples of phototrauma are sun erythema, sunburn, ephelides and reticular pigmentations. It is difficult to differentiate strictly between a physiologic and a pathologic sensitivity of the skin, but if the threshold value is greatly reduced the sensitivity is usually regarded as pathologic. This reduction in the threshold may be due to the photosensitizing effect of substances which under ordinary conditions are not present in the same quantities or do not behave in the same manner. The author subdivides the photosensitivity dermatoses into photoallergic skin reactions and photodynamic manifestations. The photoallergic reactions are best known in the temperate regions, where in some persons the allergy recurs every year with the onset of the sunny season. The terms *urticaria solaris*, *eczema solare* and *prurigo aestivalis* indicate the polymorphic and seasonal character. In the tropics these lesions are rare, because persons with a predisposition to them are unsuited to the tropics. Under incidental photoallergic reactions the author mentions those that are not connected with a previous exposure to light; that is, the diagnosis of allergy to light is based chiefly on the fact that the allergic manifestations occur on the uncovered skin. In this connection the author mentions allergic manifestation in connection with hair dyeing and alimentary photoallergy. In the photodynamic manifestations the photosensitizing substance may be naturally present, as is porphyrin. On exposure of the sensitive person to sunlight, hydroa vacciniforme and hematomporphyria develop. Another disease entity ascribed to a congenital photodynamic hypersensitivity is xeroderma pigmentosum. The photosensitizing substance can also enter the organism artificially, for instance in the form of a medicine, or it may come in external contact with the skin. In this connection the author mentions the photosensitizing effect of the eau de cologne of certain perfumes, benzine, brandy, spirit and sea water. The local form of light dermatitis are characterized by a temporary erythema and a subsequent persistent pigmentation. The form of the light effect usually indicates previous contact with a sensitizing substance in a fluid state (light dermatitis "en coulée" or light dermatitis "en brelogue"). The author reviews several case histories to illustrate the various skin disorders produced by sunlight.

81:1839-1892 (Sept. 2) 1941. Partial Index

*Polybacteriophage in Treatment of Bacillary Dysentery. J. Soesman.—p. 1863.

*Papillomatous Skin Proliferations in Genitoanal Region Caused by Amebas. R. Goenawan.—p. 1875.

Polybacteriophage in Treatment of Bacillary Dysentery.—Soesman reports 50 cases of bacillary dysentery in which he employed polyvalent bacteriophage; 17 of the patients were adults and 33 were children. The polyvalent bacteriophage was administered by mouth. The case histories indicate that the adults usually were given six times daily one ampule of 2 cc. for two days. In some patients this produced cure, but in others the bacteriophage treatment was continued for a number of days with three or less ampules. Children received in the beginning usually three ampules daily and later one ampule, but some were given larger doses. All the patients recovered, and in most of them the severe symptoms disappeared rapidly. The author concludes that polyvalent bacteriophage is a valuable asset in the therapeutic armamentarium against acute bacillary intestinal infections.

Genitoanal Proliferations Caused by Amebas.—Goenawan describes 3 cases of papillomatous proliferations in the genitoanal region. Examination disclosed the presence of *Entamoeba histolytica*, and treatment with emetine was instituted. This proved effective after previous symptomatic treatment had failed.

Devoted to the Educational Interests and Welfare of Medical Students, Interns and Residents in Hospitals

SATURDAY, JANUARY 24, 1942

Individuality and Science

Methods of education have been severely criticized for mass regulations which fail to take adequate account of individual excellences. Pedagogy has been called a racket, a pressure group which has forced legislation more in the interest of the pedagogical profession than in the interest of the individual students. Schools of education are accused of padding their curriculum in an attempt to compete in standing with other disciplines, and doctorates in education are considered inferior to those in other departments. Some of the criticisms are undoubtedly due to the difficulties inherent in the study of any subject in which the variables are difficult to control. Similar criticisms come from the so-called exact sciences, mathematics, physics and chemistry, against the difficult, less exact biologic sciences botany and zoology, and some would even deny the name of science to those most difficult studies of man's social behavior. For years the educational world has been struggling with the problem of how best to deal with the increasingly recognized differences in mental ability, differences which, like those we have found in taste reactions, are of two kinds: a difference between general marked ability and general mediocrity and a difference between ability in certain lines such as mathematics, science, art or literature.

I wrote to the sixteen living past presidents of our association and asked if they could satisfy the enclosed New York State requirements for teaching in the state secondary schools. Not one of the past presidents of the American Association for the Advancement of Science would be allowed to teach science in a New York high school without further preparation, since none had taken the required instruction, which included such subjects as the psychology, history, philosophy, principles and practice of education. One past president remarked that not all presidents would have been good secondary school teachers. It is a fact, however,

that more than a fourth have had secondary school teaching experience but could not now qualify under present requirements. This is not at the present time a serious deprivation of the freedom of these men, but some believe that the state methods of selecting teachers place undue emphasis on relatively unimportant requirements. Some educators have told us that in the balance between method and subject matter they believed the pendulum had swung too far toward method.

Uniform laws throughout the states would have certain advantages, but they might not be equally well adjusted to local environments and might prevent profitable experiments in local government. The increased means of communication throughout the world appear a mixed blessing. They tend to standardize our thoughts and behavior in a common mold but at the same time to decrease the material expressions of individuality available for social evolution through natural selection.

Opposition to totalitarianism is not merely because it attacks man's rights but also because it suppresses his personality. Individuality is the kernel of democracy, the biologic basis of the struggle for freedom. When we fight for individuality we fight on the side of nature. Recognition of individuality and all that it implies especially concerns us as scientists. Even if science should be again persecuted and driven under cover, as it was in the middle ages, there would still be some brave inquiring minds. But science cannot flourish without freedom of thought and its expression.

APPLICATIONS OF SCIENCE

Science is under fire for the suffering brought about by its applications. Science is in no position to disavow its responsibilities in the problems of peace and war. As in epidemics of disease due to the ignorance of medicine we need not less but more medical knowledge, so in seeking a cure for the scourge of war we need not less but more science. The remedy we trust may ultimately be found by that most difficult of all biologic sciences the study of

Condensation of a portion of the address of Albert Francis Blakeslee, Director of the Carnegie Station for Experimental Evolution, Cold Spring Harbor, L. I., retiring president of the American Association for the Advancement of Science, published in Science, Jan 2, 1942

motives and human behavior. Science can reply to its critics that the applications of science are merely tools which men with good or bad motives use for their good or evil ends. The same can be said of printing. Even if we admit the responsibility of science for deaths due to its applications we shall find that its applications have brought about even greater savings of life. The legend to a reproduction of the title page of Jenner's paper on vaccination published in 1798 reads "The application of the facts presented in this paper has probably saved more lives than the total of all lives lost in war." The statement is easy to believe, since it has been estimated by Haggard that in the hundred years preceding Jenner's paper sixty million people in Europe died of smallpox.

In war itself science has not been alone destructive, as may be seen from figures supplied by the Surgeon General's Office regarding the annual death rate per thousand in the United States Army for the Mexican War, the Civil War and the first World War. Deaths due to battle injuries increased from 15 per thousand for the Mexican War through 33 for the Civil War to 53 for the World War. The death rate due to disease, however, decreased from 110 through 65 to 19 for the World War. The net result is that the total death rate actually declined, from 125 in the Mexican War through 98 in the Civil War to 72 per thousand in the World War. It is a satisfaction to feel that, though implements of war have increased in destructiveness, those who are fighting to preserve our free way of life may not be subjected to greater risks than our forefathers assumed when they too fought for their country.

GIFTS OF SCIENCE TO MAN

It is not man's material comforts or even the alleviation of his physical pains which are the greatest gifts of science to mankind. Science has freed men's minds. Foremost among liberating ideas is the belief that there is order and law in the universe and that this order can be discovered by questioning nature itself. Such belief was rare in the middle ages, when processes of nature were generally attributed to supernatural causes. The Copernican theory widened our physical horizons and showed our earth a tiny speck in a universe of worlds. The theory of evolution brought a unity to our ideas of the organic world. The discovery of the mechanism of inheritance allowed an evaluation of the contributions of heredity and environment to the personality of individuals. The experimental method with adequate controls is the most valuable tool science has yet developed. Its understanding and use in daily life would mean more than all the scientific facts that schools can teach.

Science has helped to free man's soul. It has broadened the horizons of religion and given it a new point of view away from the old intolerant, materialistic theology when men sought their own salvation from selfish hope of heaven or fear of hell and persecuted or even killed those who did not conform to the authority of orthodox beliefs. Elimination of such encumbrances has left to religion a freer field for the cultivation of its great spiritual values. In this shrunken world all mankind are neighbors and our benefactions have had a world-wide view.

Science has banished much of ignorance and superstition, but much remains. Recently in a New York railway station I purchased seven different magazines on astrology. One of them, and this not the best seller according to my newsdealer, I found had a monthly paid circulation of more than a hundred and thirty-two thousand copies. The circulation of our journal *Science* is about fifteen thousand. The readers of these astrological journals are part of our democracy and help to form the policies of our government. Other examples need not be given to show that the scientific method has not yet saturated our land.

If we consider past efforts to better mankind, it is clear that good intentions are untrustworthy criteria of service to humanity. The Biblical criterion "By their fruits ye shall know them" is biologically sound doctrine and still the best test. The attempts to suppress independent thought and study of nature in the middle ages and up to the not distant past in our own country were inspired by noble motives, but they put civilization back by many centuries. The crusaders had a lofty purpose but a trivial objective: the capture of an empty tomb, with all too slight appreciation of the teachings of Him whom the tomb had held. The net result was unnecessary suffering and death even among a group of children who became involved.

VALUE OF SCIENTIFIC STUDY

During the plague of the seventeenth century when a fourth of the population of Europe died of this disease there were doubtless, as there should have been, hospitals and other organized efforts to minister to the sick. We can imagine the scant attention that would have been then paid a request for a grant for a scientific study of the life habits of such creatures as rats, fleas and the wriggling animalcules which Leeuwenhoek discovered at about this time in drops of putrid water. And yet our knowledge of rats, fleas and bacteria is one reason why centuries later pest hospitals are not found in London and we no longer dread the plague. The illustration given is an example of the unsuspected value of knowledge in apparently unrelated fields. Many other examples could be given of

the service of science to human welfare, a service which is often indirect. The ancients used human sacrifices to ensure bountiful harvests. Now we use commercial fertilizers for this purpose and find them more efficient. In the old days people fought yellow fever and smallpox by church rites and religious processions. Now we fight these diseases by killing mosquitoes and by vaccination. Formerly thousands of people were executed on the ground that they were witches. Science has proved that witchcraft does not exist.

Think where we would have been now if in the dark ages men like Copernicus, Galileo, Albertus Magnus, Roger and Francis Bacon among other inquiring minds had been able to carry on their scientific investigations in an atmosphere of intellectual freedom. Our most difficult sciences might now have reached the stage occupied by biology, for example, and we might already have found a remedy for our present sick civilization.

THE FIGHT FOR INDIVIDUALITY AND FREEDOM

Science in common with all intellectual pursuits needs tolerance, freedom from restraint and a recognition of the value of individuality. Men differ widely in their capacities for research. A great need therefore in the advancement of science, as of other intellectual endeavors, is to devise means for discovering the exceptional abilities at an early age and giving such abilities exceptional opportunities in order

that their span of effective service with its social values may be prolonged.

The public, whom science serves, knows too little what science really means. The magic and gadgetry of scientific applications rather than the methods and ideals of science make the great appeal. And yet the ideals and methods would help society reach judgments on the basis of ascertained facts rather than through emotional appeal and personal profit and would transform our daily lives if universally applied. Think what a change would come if our representatives in legislative halls should open each session with the prayer of Huxley "God give me strength to face a fact though it slay me" and really mean it.

In the promotion of human welfare through the advancement of science, scientists and the public have a common interest and may have a common share. Although each of us lives in a different and more or less separate world of his own, I trust that we shall ultimately be able to acquire a social organization as orderly as the constellations of other worlds. In our fight for individuality and freedom in this war and in the peace to come, I do not despair. The experimental method has demonstrated that we must use force without stint to show that freedom and political morality as well as personal honesty really pay. We still cherish the faith that the free search for truth by the methods of science has power to rebuild the world and will prevail.

The First Epidemic of Syphilis

In 1494 Charles VIII of France invaded Italy to make good his claims to the throne of Naples. Italy, weakened by luxury and the rivalries of her numerous states, was able to make no effective resistance, and the progress through the peninsula of Charles's army, composed of mercenaries from all parts of western Europe, was more a triumphal march of debauchery than a serious military campaign. Charles captured Naples on Feb. 22, 1495, and prepared for its permanent occupation. But dissipation and disease did what the Italians could not; a plague attacked his troops which compelled the evacuation of the city, and in the spring of 1495 the army was in undisciplined retreat from Italy. Ultimately the various disorganized troops scattered over Europe and returned to their own countries, carrying with them the new disease which thirty-five years later became known as syphilis. This was the historical beginning of syphilis. . . .

The spread of the disease can be traced in chronological sequence not only through Europe but through all the parts of the world which came in contact with Europe. The Portu-

guese soon carried it to Africa and the orient. Researches of Okamura and Susuki for Japan and China, and of Jolly and others for India, show the introduction of syphilis into these countries only after contact with Europe. . . .

The East Indian, Chinese and Japanese languages had no native names for the disease, and, like the Europeans, the orientals gave it names indicating its foreign origin. In India the disease was first recognized in 1498, after the arrival of Vasco da Gama, who had left Portugal in 1497. It appeared in Canton, China, in 1505, after the visit of Europeans. It was not recognized in Japan until 1569, when its appearance at Nagasaki was attributed to Chinese or Portuguese sailors.

There is thus an accurate historical record of the startling spread of syphilis over the known world in a few years after 1494; for this disease no name existed, and a new one invariably had to be invented. No similar record exists of the sudden establishment of any other great disease among the larger part of the earth's inhabitants.

From the History and Epidemiology of Syphilis, by William Allen Pusey, Charles C. Thomas, Springfield, Ill., Publisher, 1933.

HOUSE OF
OF THE MEDICAL

Correspondence

FAMOUS EXPLORERS

To the Editor:—On page 2287 (Dec. 27, 1941) among other questions relating to pioneer physicians you ask "Do you know what physician was a famous explorer?" The answer given on page 2290 is David Livingstone (1813-1873), the fearless Scottish medical missionary.

Livingstone arrived at his first missionary station on July 31, 1841 and remained a missionary at Mabotsa until 1846. With his family he traveled to several places investigating sites for missionary work and was undoubtedly the first white man to reach Lake Ngami, Aug. 1, 1849. His work as an explorer really began on June 8, 1852, when he parted from his family and left Cape Town, still in the service of the London Missionary Society, and he continued this connection with this society until 1857. The Zambesi expedition "for exploring eastern and central Africa," of which he was commander, left Liverpool March 10, 1858, a year after the death of Dr. Elisha Kent Kane, one time of the Medical Corps of the U. S. Navy, whom I consider an equally famous, though American physician, explorer.

Elisha Kent Kane (1820-1857), born at Philadelphia, was graduated in medicine from the University of Virginia in 1842. He entered the Medical Corps of the U. S. Navy in 1843. His first cruise took him to

the China station, and en route he explored the country from Rio de Janeiro to the base of the Andes. He visited India, traveling from Bombay to Ceylon. On the arrival of his ship in China he provided a substitute and started for Luzon in the Philippine Islands. Returning home in 1844 he traveled via India, Persia, Syria, Egypt, Greece, Austria, Germany and Switzerland, reaching the United States in 1846. In 1847 he was with the expedition to Mexico. In 1850 he was surgeon to the first Grinnell expedition to the arctic regions to search for Sir John Franklin. This expedition failed to find Franklin, though Kane wrote a book, published in 1854, describing the search. The second Grinnell expedition sailed in June 1853 with Dr. Kane in command. He sailed through Smith Sound to the sea now known as Kane Basin, thus establishing the route for several future arctic expeditions. This expedition spent two winters in the arctic regions, finally abandoning the ship, and after great hardships reached Upernivik, Aug. 5, 1855. The highest point north was latitude 80° 35' (June 1854). In recognition of his services as an explorer, Kane received the Founder's Medal of the Royal Geographical Society, a gold medal from the Paris Geographical Society and a medal from the Congress of the United States. He died at Havana, Cuba, Feb. 16, 1857.

RICHMOND C. HOLCOMB, M.D., Upper Darby, Pa.
Captain, M. C., U. S. Navy, retired.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items for consideration for publication in the Student Section.

Students and Interns Pledge of Allegiance

At the joint national convention of the Association of Medical Students and the Interne Council of America in Chicago, December 27-29, the delegates signed a pledge of allegiance to the government of the nation, which reads as follows:

A PLEDGE OF ALLEGIANCE

TO THE PRESIDENT OF THE UNITED STATES, COMMANDER IN CHIEF OF OUR ARMED FORCES

The American people are at war, compelled to take up arms in self defense against Axis aggression. Together with all free nations and freedom loving people, we are fighting to maintain our right to live among our world neighbors in freedom and in common decency, without fear of assault.

In this grave hour, Mr. President, we pledge to you, and through you to our government and nation, our allegiance. We pledge that we shall not be found wanting in our readiness to give everything, our energy, skill and lives, to carry through all the duties we are called to perform in assuring victory to our just cause in this war.

WE MEDICAL STUDENTS AND INTERNS PLEDGE TO YOU, MR. PRESIDENT:

1. To take our place, side by side with the rest of the American people, in the armed forces of our country; to enlist at once in the medical corps and Medical Reserve Corps of the United States Army and Navy.
2. To prepare ourselves for military service by premedical training.
3. To work longer and harder at the task for which we are best fitted; to equip ourselves completely for the job that lies ahead; to support and assist our government and deans in the task of putting our schools and curriculum on a war footing.
4. To give our services in the defense of the civilian population of our country; to help the American Red Cross train our people in first aid; to strengthen the casualty squads in our hospitals.

The individual signed pledges were presented to Dr. Morris Fishbein, editor of THE JOURNAL, with a request that they be forwarded to the President of the United States. Dr. Fishbein has forwarded the signed pledges to Major Sam F. Seeley, executive officer of the Procurement and Assignment Service, Washington, D. C., for transmission through the proper channels to the President.

Check on Eating Habits of Students

Wayne University, Detroit, has appointed a faculty committee on nutrition to instruct students in the dietary necessities of health during the emergency. The chairman is Vaughn S. Blanchard, M.S., head of the department of health and physical education, and the members are Mrs. Jean Tripp, president of the Detroit Dietetic Association, and the following Wayne faculty members: Frances B. Sanderson and Lillian Meyer of the home economics department; Dr. Arthur H. Smith of the College of Medicine; Dr. Irvin Sander, director of the Student Health Service; Counselor Doris Cline, Ph.D., of the Division of Student Personnel; Dr. Frank Oktavee, professor of health education, and Lillian Wakefield, cafeteria manager. The committee has made an extensive check of the daily trays in the university cafeteria to determine the nutritive value of meals selected. The data found in this study will be the basis of displays in the corridors showing luncheons that are nutritionally good and those that are bad; other work is in progress to help students arrange next semester's class schedules with an eye to regular and adequate lunch periods.

University of Minnesota Medical School

Clinical teaching at the University of Minnesota Medical School, Minneapolis, is done primarily in the University Hospitals and outpatient department and the Minneapolis General Hospital. Some clinics are held in the eight hundred and sixty-seven bed Ancker Hospital and the two hundred and fifty bed Gillette State Hospital for Crippled Children in St. Paul. Certain elective clinics are held also at the Southtown Clinic, the Shriner's Hospital for Crippled Children, the Salvation Army Home and various settlement houses and centers in Minneapolis and the Wilder Dispensary in St. Paul.

The facilities of the medical school limit the number of students to about one hundred freshmen each year, selected by an admissions committee, native residents of Minnesota being given first preference, while second preference is given to applicants from the North Central states. Applicants from other sections are accepted only for special reasons, the most common being that they are outstanding students and sons and daughters of alumni of the University of Minnesota.

The present requirements for admission are three years of college work and courses in physical chemistry, psychology, genetics and eugenics, in addition to the science courses required previous to 1939, at which time the new requirements for admission went into effect. The University Hospitals include under one roof the Elliot and Todd Memorial hospitals, the

Memorial Cancer Institute, the Eustis Children's Hospital, the Psychopathic Unit and the Students' Health Service, providing a total capacity of four hundred and eighty beds and thirty bassinets and a general outpatient department caring for nearly 400 patients a day.

The medical school is conducted on the four quarter system, but freshmen are received only at the opening of the fall and winter quarter. The school was organized in 1883 as the University of Minnesota College of Medicine and Surgery, at which time its only function was to conduct examinations for the degrees of M.B. and M.D. With the absorption of the St. Paul Medical College and the Minnesota Hospital College in 1888, it was reorganized and a class has graduated each year since 1889. In 1908 the Minneapolis College of Physicians and Surgeons was absorbed, and in 1909 the University of Minnesota College of Homeopathic Medicine and Surgery. The present title of the school was assumed in 1913. In 1914 a committee was appointed by the administrative board to consider the possible relationship of the Mayo Clinic to the medical school, but it was not until the following year that the Board of Regents effected an affiliation, not with the medical school direct, but with the graduate school of medicine. Two years later this temporary affiliation was replaced by permanent union, with transfer to the university of the endowment fund so generously provided by Drs. William J. and Charles H. Mayo for the

support of the Mayo Foundation. The graduate school of medicine offers opportunity for study and research in the medical school in Minneapolis and in the Mayo Foundation for medical education and research at Rochester, Minn. The University of Minnesota Medical School, in cooperation with the Mayo Foundation, has pioneered in graduate medical education. The number of graduate students has increased until there are about six hundred registered for major and minor work in the medical sciences, a number so large that it is causing problems of facilities and staff. From 1915 to 1938 the state legislature appropriated \$25,000 annually for medical research, which was allocated to faculty members for research projects by the dean of the graduate school on recommendation of the medical graduate committee.

In 1938, with a grant from the Commonwealth Fund of New York, a department of postgraduate medical education under the directorship of Dr. William A. O'Brien was created. The Center for Continuation Study in connection with this department affords practicing physicians an opportunity to attend organized courses. During the current and the next two years the Commonwealth Fund will supply \$8,000, \$6,000 and \$3,000 for the continuation of this program.

Recently the Minnesota Medical Foundation has been incorporated not for profit for the purpose of promoting the welfare of the community by the cooperation of alumni and friends of the medical school in improving the undergraduate, graduate and research functions of the university; to establish scholarships, lectureships, professorships, research and student loan funds and in general to advance the interests of the medical school and its alumni. This foundation gets its funds from gifts of patrons and members, from bequests and donations, and from membership dues. Its membership includes not only alumni but laymen interested in the progress and standards of medical service in this area.

Medical Students' Association and Intern Council Merge

At a joint meeting of the Association of Medical Students and the Intern Council of America in Chicago, December 27-29, the two organizations decided to merge into a new joint organization which will be called the Association of Interns and Medical Students. The objects of the new organization as stated in its constitution are to "concern itself with the ethical, social, humanistic and educational aspects of medicine in order that its members may be better equipped to serve themselves, their profession and society." The president of the joint organization is Thomas L. Perry Jr. of Harvard Medical School, who last year was president of the Association of Medical Students. The membership of the Association of Interns and Medical Students now amounts to about six thousand. The general theme of the annual meeting was "Health and Defense of the Nation." The delegates discussed ways of implementing the national effort. At the panel on medical education it was urged that the medical curriculum and internship be streamlined to meet the urgent need for physicians, that courses in military medicine be included in the curriculum and that the present high standards of medical education be maintained. Other discussions concerned the housing, food, health, recreational and financial problems of medical students and interns, the training of medical students and interns in first aid for service in the civilian defense program, the organization of hospitals into catastrophe squads and mobile hospital units, and cooperation of the armed forces. Among the speakers at various sessions in addition to those mentioned in the Student Section, Dec. 27, 1941, were

Col. Charles G. Hutter, M. C., U. S. Army, liaison officer of the Army to the American Medical Association; Commander Mott of the Navy Medical Corps; Dr. Victor E. Johnson, dean of the medical students of the University of Chicago; Dr. Alfred Korach of the University of Cincinnati College of Medicine; Dr. Herman Bundesen, president of the Chicago Board of Health; Dr. Arthur C. Bachmeyer of the Association of American Medical Colleges; Dr. William D. Cutler, secretary of the Council on Medical Education and Hospitals, and at the banquet Mr. Chang Lok-Chen, Chinese Consul-General of Chicago; Mr. R. W. MacKay, who represented the British Embassy and Mr. D. I. Zaikin, Russian vice consul of New York City.

Northwestern

A Student Medical Society comprising all the students of Northwestern University Medical School, Chicago, is being organized with the first of this year. Under the sponsorship of the student-elected Pi Kappa Epsilon honorary fraternity, four meetings will be held each quarter. By the organization of a medical society it is conceivable that medical students may derive considerable benefit from actual participation in the activities of their own society. Because of the almost universal practice by members of the profession of meeting in groups to exchange information, training in the art of expressing the results of clinical or scientific study may well be included in the education of a medical student. The first meeting will be made up of nine talks on three general subjects by students interested in particular features of each.

Northwestern now has a department of visual education, substantially endowed and called the Laura Shedd Schweppe and Charles H. Schweppe Fund for Visual Education. The objective of this Fund is to create a library of moving picture films for use in the classroom or meetings as an additional aid to student training. The endowment provides also that films on any medical subject may be purchased, and it will cover the expenses of films made by members of the Northwestern faculty. These films will be organized and planned as to subject matter by a committee composed of the dean, two departmental heads and two senior medical students. The ideal film will be composed of several 100 foot individual reels relating to one medical problem, one reel being devoted each to the anatomic, physiologic, pathologic, medical and surgical aspect of the problem. A trained animator is available to clarify the presentation of the subject matter through the medium of animated diagrams and figures.

Military Service and the Physiology Department at Washington University

Three members of the staff of the physiology department of Washington University School of Medicine, St. Louis, having been called to active military service, Drs. Joseph Erlanger and Arthur S. Gilson of the departmental staff were assisted in the course of lectures in physiology, just completed by the following distinguished physiologists from other schools: Dr. Anton J. Carlson of the University of Chicago, who lectured on endocrine and gastrointestinal physiology; Dr. Carl J. Wiggers of Western Reserve University School of Medicine, Cleveland, on the physiology of the vascular system, and Dr. Robert Gesell of the University of Michigan Medical School, Ann Arbor, on respiration. Dr. Thomas P. Findley Jr. of the department of medicine lectured on renal function.

A special lecture was delivered before the student body and faculty, December 3, by Dr. William Boyd, professor of pathology and bacteriology at the University of Toronto Faculty of Medicine, whose sub-

ject was "Increasing Incidence of Disease, with Special Reference to Carcinoma of the Lung."

The junior class was given the first of two comprehensive examinations, December 6, designed to cover the two years of preclinical work; the other comprehensive examination to cover the first three years' work will be given in the spring.

A capacious student lounge and reading room was opened in December.

Four Boston Schools Go on Twelve Month Basis

As a war emergency measure, Boston University School of Medicine, Harvard Medical School, Tufts College Medical School and the new Harvard School of Dental Medicine announced, Dec. 29, 1941, in a joint statement that beginning on July 1, 1942 they will go on a twelve month basis. The new program of continuous operation will do away with the present summer vacation and will shorten the period of medical training to three calendar years instead of four. Graduates of the new Harvard School of Dental Medicine will qualify in four and one-half years instead of five, as originally planned. No change in the total amount of required work is contemplated in any of the institutions involved, and there is no intention to lower the standards of education in these important fields. This change is a part of the general emergency program being installed throughout Harvard University, Tufts College and Boston University to accelerate the education and training of students who may be called into service.

Military Preparedness Symposium for Medical Students

An all day symposium on military medicine, chiefly for the benefit of the third and fourth year students at the Long Island College of Medicine, Brooklyn, held on December 3, was designed to stimulate applications among the two classes of medical students for commissions in the medical administrative corps; also to give them a survey of factors involved in various branches of military medical service. Among the speakers were Capt. Dickinson S. Pepper, M.C., U. S. Army, now at Walter Reed General Hospital, Washington, D. C.; Rear Admiral Charles M. Oman, U. S. Naval Medical Center, Washington, D. C.; Capt. Paul M. Albright, in charge of personnel in the reserve section of the Bureau of Medicine and Surgery of the Navy, Washington, D. C.; Lieut. John K. Hawes, examiner on the Naval Aviation Cadet Board, Floyd Bennett Field, and Dr. Philip D. Wilson, chief surgeon of the Hospital for Ruptured and Crippled.

New York City Hospitals Modify Internships

Dr. Willard C. Rappleye, commissioner of hospitals, announced, January 11, that in view of the urgent needs of the Army and Navy the municipal hospitals of New York will modify their internships to a one year period of training in order to assist in the recruitment of medical officers for the armed services. The general plan contemplates that the basic internship will be one year. Those who complete that service and are not eligible for a commission, because of physical defects or other reasons, may remain as residents either in the general services or in a special service.

The commissioner also stated that a certain number of residents will probably be permitted to continue their advanced training in special fields of medicine in order to insure a sufficient supply of specialists for the armed services and for civilian needs in the future.

The Department of Hospitals and its advisory council are advising that all interns and residents eligible for military duty be urged to apply for a commission in the Medical Corps of the Army or the Naval Medical Corps Reserve. Under the rules of the Selective Ser-

vice System, the local boards ordinarily will not defer interns beyond twelve months of hospital training. Residents and interns who do not apply for commissions will automatically come under the provisions of the Selective Service System and their cases will be disposed of in the usual manner by local boards.

Under the new program of the Procurement and Assignment Service, advisory committees will be set up in each corps area of the United States to assist in the recruitment of medical personnel for the various government services and also to select residents and others for advanced training in special fields or to help protect essential hospital services in the local communities. On these advisory committees are representatives of the hospitals, medical schools and the medical, dental and veterinary professions.

Professor of Anatomy to Retire at Washington University

Dr. R. J. Terry will retire next June as head of the department of anatomy at Washington University School of Medicine, St. Louis, and will be succeeded by Edmund V. Cowdry, Ph.D., professor of cytology, whose department will be combined with the department of anatomy. Dr. Terry was born in St. Louis and in his long teaching career has instructed about 3,000 medical students in anatomy. He was a member of the National Research Council from 1921 to 1927 and formerly was president of the American Association of Physical Anthropology and of the St. Louis Academy of Science. Alumni three years ago presented his portrait to the school and set up a fund in his name to be used for research in anatomy. Dr. Cowdry has been on the faculty since 1928. He has served on commissions studying yellow fever; two years ago he was appointed director of research at Barnard Free Skin and Cancer Hospital, St. Louis. He has been a member of scientific expeditions to Alaska, Japan, Kenya Colony, Africa, Russia and South China. He taught anatomy at Peiping Union Medical College for four years and was an associate of the Rockefeller Foundation in New York.

Student Activities at Maryland

Under the direction of the Student Council, the new program of student activities at the University of Maryland School of Medicine, Baltimore, has entered its second year. The program has social as well as educational aims, and each student is assessed a fee to support the program. The first event in the current school year was an evening of motion pictures on thoracic surgery, which were discussed by Dr. Thomas B. Aycock, professor of clinical surgery. The social side of the program got under way, October 25, with a dance welcoming the freshmen. With the fees thus provided, a lounge has been fitted out to provide a comfortable place for students to congregate and relax. Refreshments are sold here. The students' lounge has already become popular.

Duke Goes on Twelve Month Schedule

To accelerate the medical course for the war, the executive committee of Duke University School of Medicine, Durham, N. C., decided on Dec. 17, 1941 that all present Duke medical students should attend summer quarters, i. e. a continuous twelve month medical course with vacations from Dec. 20, 1941 to Jan. 5, 1942, March 21 to March 30, April 6, June 13 to July 6, September 19 to October 1 and Dec. 19, 1942 to Jan. 4, 1943. The second year course in pathology will commence on July 6, 1942. The incoming first year class will register on July 6, 1942 instead of

Oct. 1, 1942. Thus Duke will go on a continuous twelve month schedule, degrees will be granted at the end of three years and the admission of a first year class will take place every nine months.

The Donnelley Scholarship Fund at Yale

The dean of Yale University School of Medicine, New Haven, Conn., announced on November 24 the establishment of a scholarship fund in memory of Reuben H. Donnelley, former vice president of R. R. Donnelley & Sons Company of Chicago. Beginning this year, a student selected each year primarily because of his character, capacity for leadership, promise of future usefulness, scholastic standing and financial need will receive from this fund an award of from \$1,000 to \$1,500. The grants will be made for one year only but may be renewed for succeeding years or distributed to a larger number of the students at the discretion of the faculty.

Yale Goes on Twelve Month Basis

The Yale University School of Medicine, New Haven, Conn., announced, December 30, that it will operate the year round for the duration of the national emergency. The course will thus be shortened from four to three years, and each year will comprise four terms of eleven weeks. Tuition for the full course will remain unchanged at \$2,000. Because of the reduction in time for elective work, the thesis requirement will be waived for classes graduating in 1943 and thereafter under the three year plan, the announcement said, but the thesis will be continued as an elective. It has also announced that provision had been made to increase the enrollment of each entering class from fifty to sixty. The summer term will begin June 29.

New Teaching Unit at Georgia

The Wilkenford Hospital is expected to be open before the new year, providing about fifty beds for the tuberculosis unit of the University Hospital at the University of Georgia Medical School, Augusta. The maintenance of this hospital, which formerly was a private hospital for women and children, will be shared by the State of Georgia, the County of Richmond and the City of Augusta. The clinical supervision will be in charge of Dr. Lucius N. Todd, professor of tuberculosis. The annex to the Newton Building also will be completed before the new year and will provide a 50 per cent increase in floor space for the laboratories for clinical diagnosis and micro-anatomy.

Smith-Reed-Russell Society

At the annual meeting of this honorary group at George Washington University Medical School, Washington, D. C., January 15, the principal speaker was Elmer Louis Kayser, Ph.D., professor of European history and dean of the university. The president of the organization, Gilbert Anderson, presided. Cloyd H. Marvin, Ph.D., president of the university, gave the address of welcome, and Dr. Walter A. Bloedorn, dean of the school of medicine, introduced the new members including honorary initiates Brig. Gen. Shelley U. Marietta, U. S. A., M. C., commanding officer of Walter Reed General Hospital; Dr. Claude M. MacFall of the department of anatomy at the university, and Dr. Harry F. Dowling, clinical professor of medicine at the university. The student members initiated were: seniors, Morton J. Folston, Joseph N. Hamm, Marvin P. Footer, Miss Shirley F. Pearlman, Charles J. Wallace Jr., and Anthony Zappala; juniors, William Robert Perkins Jr., Roy A. Petersen, Charles H. Place Jr., Boris Rabkin, James S. Reitman, Solomon Resnick, Leo

H. Siegel, Herrick M. Thomas, William K. Barton, Kenneth E. Blundon, Andrew P. Dedick Jr., John P. Docktor, Milton Dorfman, Samuel Dove, Benjamin F. Edwards, John A. Edwards, Richard H. Fischer, Edwin H. Weitzen, Dorothy S. Sislen, Sally L. Steele, Daniel J. Stone, Herbert H. Goldstein, Milton H. Hollander, Carlos F. Jimenez-Torres, Stanley W. Kirstein, James W. Long, Gordon R. MacDonald and Miss Theodora L. Peck.

A number of prominent persons in the scientific and military groups in Washington were invited as special guests to the banquet.

Indiana Selects Entering Class Earlier

Indiana University School of Medicine, Bloomington, will select the next entering class of students February 3 instead of in May, as heretofore, in order to speed up medical training to meet the war emergency, according to an announcement by the dean, Dr. Willis D. Gatch, January 5. This will make possible the beginning of training of the entering class in the summer session rather than in the fall. According to the announcement, there will be a 10 per cent increase in the number of admissions over those admitted last year for the same reason. The chairman of the faculty committee on admissions will be Dr. Carl H. McCaskey, Bloomington.

Louisiana Students Apply for Army and Navy Commissions

Recently 80 per cent of the juniors and 76 per cent of the senior students at Louisiana State University School of Medicine, New Orleans, who are eligible have applied for or have received commissions in the U. S. Army or Navy or Public Health Service, so that they may be available for service to their country on completion of their medical training. There was a total in the junior class of seventy-six eligible to apply for commissions and in the senior class a total of seventy-nine eligible.

New York University

On Dec. 8, 1941, the day on which war was declared on Japan by the United States, the student body of New York University College of Medicine, acting through its Council, signified its eagerness to serve in whatever capacity the students might be needed. During the week of January 5 special training was begun to prepare them to render maximum service. Lectures were scheduled on first aid and military medicine. The latter series will continue throughout the rest of the academic year.

The McLean Research Award at Wayne University

The first recipient of the Dr. Angus McLean Award for Research will be Dr. Robert Mayo Tenery, a resident and fellow in surgery at Presbyterian Hospital, New York. Last year Dr. Tenery was a research fellow in the department of surgery at the Wayne University College of Medicine, Detroit, where he worked on blood changes after excessive burns. The award, provided by the widow of Dr. McLean, will be presented annually by the Wayne University chapter of Nu Sigma Nu medical fraternity.

North Carolina

At the opening meeting of Alpha Epsilon Delta honorary premedical fraternity at the University of North Carolina, Chapel Hill, this fall, given in honor of the freshmen premedical students, the principle speaker was Dr. Grant L. Donnelly of Chapel Hill.

Book Notices

Medical Diseases of War. By Sir Arthur Hurst, M.A., D.M., F.R.C.P., Consulting Physician to the Salonica Army. With the cooperation of H. W. Barber, M.A., M.B., F.R.C.P., Physician in Charge of the Skin Department, Guy's Hospital, London, et al. Second edition. Cloth. Price, \$5.50. Pp. 427, with 48 illustrations. Baltimore: William Wood & Company, 1941.

This rather small book is a revision of Hurst's *Medical Diseases of the War* published in 1916. The collaborators mentioned have assisted in bringing it up to date. The brief chapter on skin diseases is included because "no less than 30 per cent of medical casualties in the British Expeditionary Force in the last war were the result of scabies and pediculosis." Transmissible diseases discussed carefully and well, although briefly, include amebic and bacillary dysentery, typhoid (paratyphoid) and trench fevers, meningitis, tetanus, infectious jaundice and malaria, which "easily took first place in diseases responsible for casualties in 1914-1918." A short chapter is devoted to gas poisoning. It is surprising to note that about 20 per cent of the men discharged from the British army at present have peptic ulcer. Approximately 90 per cent of these ulcers had been present before induction of the soldiers into the army. Nearly a third of the book is devoted to a good discussion of the various types of war neuroses, hysterias and anxiety states. Emphasis is laid on the importance of prompt "simple psychotherapy in the form of explanation, persuasion and reeducation." The book is well written; it reads easily and should prove especially helpful to those interested in military medicine. Students and practitioners also will find it well worth an evening's perusal.

Further Therapeutic Tests with an Anti-Leprosy Serum (in Netherlands East Indies and Other Countries). By John Reenstierna, M.D., Professor of Hygiene and Bacteriology at the University of Uppsala, Sweden. *Acta medica Scandinavica, Supplementum CXVIII.* Paper. Pp. 195, with 17 illustrations. Uppsala: Almqvist & Wiksells Boktryckeri-A.-B., 1941.

This book is of scientific interest only to the leprologist or the student of tropical medicine. It consists of introductory remarks and three parts. Part I contains the English version of about 200 cases treated with the author's anti-leprosy serum together with the critical comments of the author. Part II consists of the same case reports in their original languages, particularly Dutch. Part III is an illustrative background of seventeen plates with explanatory notes. During the years 1933 to 1937 the anti-leprosy serum of Reenstierna had been tested in several cases of leprosy in Sweden, Ethiopia and Colombia, with reported favorable action on certain manifestations of the disease. The present work is a follow-up on a larger number of cases in seventeen additional countries. The principal work was done in the Netherlands East Indies, where 92 patients were treated. In almost all cases the treatment comprised a single course of three intragluteal injections of 10 cc. of anti-leprosy serum given within one week's time. The great majority of patients given this serum were previously and subsequently treated with chaulmoogra oil or its derivatives. It is shown that, following the serum therapy, there was frequent and rapid improvement in certain leprosy manifestations, including nasal, trophic and other ulcers, loss of sensation and paralysis of eyelids and fingers. Subjective improvement in mastication, smell, taste and sight is also recorded. In the majority of cases, results are reported a few days after treatment. There are few prolonged observation reports to show the duration of the improvement. The author feels that the improvement may be only temporary; he states that "a cure through serum treatment alone of such a chronic disease as leprosy caused by a resistant micro-organism is highly improbable." He advocates alternating chaulmoogra oil and other measures of treatment with his serum, since he regards it as only a good auxiliary to the standard therapy. The improvements which are shown rapidly to follow his serum therapy he does not consider "spontaneous" amelioration. The function of the seventeen plates made before and after treatment is to show the extent of improvement. The time interval between these pictures in all cases is short, vary-

ing between a few days and six weeks. The illustrations are, for the most part, clear, but they are not always conclusive as to the amount of improvement which has taken place and they certainly fail to show the permanence of this improvement. At the Carville Federal Leprosarium, the anti-leprosy serum made according to Reenstierna's specifications was used on 4 patients with a like number of controls. No improvement was noted in any of the leprosy manifestations, and the results, entirely negative, were published only in the annual report of the institution.

Preeclamptic and Eclamptic Toxemia of Pregnancy. By Lewis Dexter, A.B., M.D., Research Fellow in Medicine, Harvard Medical School, Boston, and Soma Weiss, A.B., M.D., Hersey Professor of the Theory and Practice of Physic, Harvard University. In collaboration with Florence W. Haynes, Herbert S. Sisc and James V. Warren. Cloth. Price, \$5. Pp. 415, with 45 illustrations. Boston: Little, Brown & Company, 1941.

This book has been written by internists. The senior author has had some fifteen years' experience as a medical consultant in an obstetric service, and presumably the junior author and other assistants have likewise had contact with an obstetric service. The authors modestly voice their hope of clarifying certain confused issues and to point the way to further knowledge. This they have done. There is much of an intriguing nature, and all of the material is stimulating. The chapter on the history of eclampsia with its portraits of Mauriceau and Puzoz is interesting. It shows that even at the beginning there were two schools of thought, the interventionists and the non-interventionists. Meticulous care of definitions is made. The authors distinguish between an edema in normal pregnancy and one in toxemia of pregnancy. For the animal experiments cats and rabbits were used, and there are presented the results of the exhibition of several hormone preparations, of the findings of pressor substances in the placenta, amniotic fluid and normal rabbits' kidneys. The monograph is based on a study of 100 normal pregnant patients, 100 pregnant patients with edema and 80 pregnant patients with varying degrees of hypertension. The authors feel that a careful study of a limited number of patients is of more value than a less careful study of a larger number. Only 42 of the patients with toxemia were followed for a period of six months or longer. Since only 80 patients with toxemia were studied, it is perfectly possible that some points are over-emphasized and others underemphasized. For example, 39 patients had a pre-pregnant hypertension and, since over one half of these had no increase in blood pressure during the pregnancy, the authors conclude that pregnancy does not cause further damage to a patient with hypertension. This is not the general experience of the obstetrician. The authors also describe toxic effects of pituitary resulting in possible death from circulatory collapse in several and from cortical necrosis of the kidneys in one patient. Such toxic effects have not been the experience of most obstetricians who use solution of posterior pituitary freely. The treatment recommended by the authors is properly that used at two of the maternity hospitals in the United States. The bookmaking is excellent as to paper and type, the quality of the illustrations and tables. The subject matter is presented clearly, logically and in good plain English.

Epilepsy and Cerebral Localization: A Study of the Mechanism, Treatment and Prevention of Epileptic Seizures. By Wilder Penfield, Litt.B., M.D., D.Sc., Professor of Neurology and Neurosurgery, McGill University, Montreal, and Theodore C. Erickson, M.A., M.Sc., M.D., Associate Professor of Surgery, University of Wisconsin. Chapter XIV by Herbert H. Jasper. Chapter XX by M. R. Harrower-Erickson. Cloth. Price, \$8. Pp. 623, with 163 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

The last wholly satisfactory book on epilepsy was written by Gowers sixty years ago, with a second edition which appeared twenty years later. Books in English written since then have been of specialized interest. The best of these is probably the present volume by Penfield and Erickson. It misses the rounded excellence of Gowers because it views epilepsy through the peephole of the neurosurgeon. Nevertheless, in the field in which the authors excel, the diagnosis and surgical treatment of "symptomatic" or of traumatic epilepsy and the cortical localization of symptoms experienced by the epileptic, the book is certainly the best available.

"Cerebral Localization" should perhaps have appeared first in the title, because the authors' contributions which are most original deal with the phenomena observed after electrical stimulation of the exposed cortex of conscious patients who are being operated on for the relief of epilepsy. Patients have cooperated gladly in these studies, for, as Aretaeus the Cappadocian remarked, "their good hopes render them strong in endurance." Cortical stimulations which result in symptoms or in seizures similar to those usually experienced by the patient indicate the place of origin and the pathway of spread of spontaneous seizures. These observations are of great importance in understanding the physiologic anatomy of many of the sensory and motor symptoms involved in epileptic seizures. This knowledge in turn is essential for the neurosurgical treatment of epilepsy. The authors recommend the radical excision of scars which involve the brain substance and give the results on seizures in 165 cases in which operation was performed. The operative mortality was 4 per cent. These matters, abundantly documented by drawings, photographs and detailed case histories, occupy about one half of the volume. A chapter of seventy-five pages written by Herbert Jasper describes electroencephalography and the contribution of this technic to the localization of brain lesions. A thirty page chapter by M. R. Harrower-Erickson discusses psychologic aspects, especially the use of the Rorschach test. Patients with symptomatic epilepsy are the main beneficiaries of the Montreal studies. However, these comprise but a minority of the army of epileptic patients. The authors give some attention, about one sixth of the volume, to the majority group of essential epilepsy and their medical treatment. These chapters, being reports of the work of others, do not maintain the originality and value of the rest of the book. Among drugs, bromide receives six pages, phenobarbital five and phenytoin sodium three. The bibliography comprises some eight hundred references. This volume can be recommended to neurologists, neurosurgeons, physiologists and all who are concerned with the working of the human brain and with epilepsy.

Roentgen Diagnosis of the Extremities and Spine. By Albert B. Ferguson, M.D. *Annals of Roentgenology, A Series of Monographic Atlases, Volume XVII.* Enlarged first edition. Cloth. Price, \$12. Pp. 462, with 562 illustrations. New York: Paul B. Hoeber, Inc., 1941.

The publication of a monograph makes the author more liable to criticism as to the choice of material or the space devoted to certain subsections of the general topics than might be expected in case of a book by many authors. Minor criticisms cannot detract seriously from the general value of this excellent monographic atlas. The illustrations constitute a valuable collection of reference material with a brief but succinct illuminative text. Especially interesting is the section devoted to the lame back. Members of the American Medical Association who have seen the Lame Back Exhibit at recent meetings will prize this material as constituting a detailed reproduction in handy form for study. Evidently the author shares the opinion gradually gaining ground that it should be possible to make a clinical diagnosis of posterior protrusion of an intervertebral disk with sufficient surety to indicate the need of surgical exploration or of surgical fusion, without the necessity of injecting air or iodized oil into the neural canal. The opening chapter on the analysis of roentgenograms should be read by every radiologist and diagnostician dealing with bones and joints.

Beiträge zur Röntgendiagnostik der Otitis media acuta und ihrer Komplikationen im Schläfenbein. Von Sölve Welin. *Acta Radiologica, Supplementum XLII.* Paper. Price, 20 Swedish kroner. Pp. 180, with 105 illustrations. Lund: Håkan Ohlssons Boktryckeri, 1941.

The author has developed into a monograph his investigations and clinical observations on the value of the roentgen study in the clinical study of acute otitis media. The increasing general use of the roentgen ray in otolaryngologic diagnosis has enabled him to accumulate material amounting to 926 patients diagnosed as having acute middle ear disease between the years 1934 and 1939. The objects of this investigation were (1) to determine the value of the various roentgenologically demonstrable changes and especially the diagnostic and prognostic value of reduced lime content in the mastoid intercellular septums, (2) to ascertain the diagnostic possibilities in the roentgen evidence of the different complications of acute mastoiditis which are associated

with pathologic and anatomic changes of the temporal bone and (3) to show how early in life the cells of the temporal bone can be demonstrated roentgenologically and what value the roentgen evidence offers from the clinical point of view, even at birth. In developing the study of these topics the author devotes chapters to a historical review of the subject, to a satisfactory discussion of technic, giving in detail the instructions for the various projections of the mastoid cells commonly employed, a detailed study of the roentgen anatomy and roentgen pathology of the mastoid region, concluding with a clinical section in which are set forth the details and illustrative roentgenograms of a great many interesting case reports. A complete bibliography is appended. The author is thoroughly convinced of the clinical value of the roentgen ray study in the diagnosis of acute mastoid disease and its complications and declares that even as early as birth the developing cells are roentgenologically demonstrable and that the roentgen examination is of value in acute middle ear infection in nurslings and children as well as in adults.

A Short Account of an Anti-Leprosy Serum and Its Therapeutic Value. By John Reenstierna. Paper. Price, 3 Swedish kroner. Pp. 32, with 10 plates. Uppsala: A.-B. Lundequistska Bokhandeln; Leipzig: O. Harrassowitz, 1941.

This brochure is a recapitulation of the author's previous publications on the subject. Reenstierna is of the opinion that the acid fast bacilli of both Hansen and Koch are only evolutionary forms of a lower fungus of nature which in the distant past adapted itself to the human organism. He seems convinced that Kedrowskij in 1900 and he himself in 1912 cultured the true Hansen bacillus. Their cultures at first showed only non-acid fast micro-organisms, but later the majority appeared to be of acid fast forms. By growth in toluene glycerin bouillon a culture is obtained which can be used to immunize sheep. The author gives in detail his technic for the production of the anti-leprosy serum. All the case records and illustrations used have appeared in previous publications. The rapidity of the therapeutic action claimed for the serum in such a chronic disease as leprosy and the limitation of this action to the minor manifestations of the disease do not seem to be strong evidence for its specificity. There are postexamination reports on 41 cases. These reports often do not state the interval of time that has elapsed since treatment. These reports are not very extensive or descriptive and in most cases leave the reader in doubt as to the permanence of the improvements attributed to the anti-leprosy serum.

The Essentials of Occupational Diseases. By Jewett V. Reed, B.S., M.D., F.A.C.S., and A. K. Harcourt, B.S., M.D. Cloth. Price, \$1.50. Pp. 225. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

Much useful information derived from a great variety of authentic sources on symptoms, diagnosis and treatment has been collected in this compendium on the occupational diseases. Prevention is not discussed. The interesting observation is made that medical management of occupational diseases is frequently complicated because the patient more often than not has already made his own diagnosis. The authors contend, therefore, that physicians should be cautious about advancing opinions regarding the existence or nonexistence of a disease unless they are reasonably familiar with possible exposures in the working environment. Only after such consideration do the physical and laboratory findings assume real value.

The Twentieth Century Fund. Twelve Years' Review—1929-1940 and Annual Report 1939 and 1940. Paper. Price, 65¢. New York, 1941.

During the twelve years since 1929 the Twentieth Century Fund has devoted its resources to determining economic policies and furnishing economic leadership. This is staking out a rather wide claim. It is hard to find facts to indicate that public policies in such fields as economic sanctions, debts, stock market, big business, government credit, collective bargaining and housing have been greatly affected by the studies of this foundation. Certainly its contribution to the Committee on the Costs of Medical Care and publications in this field were not responsive. It seems to be implied, for the fact that "certain medical societies themselves, especially in the Northwest, have set up a periodic payment plan. . . ." During these twelve years the fund has expended \$1,942,006.04.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TYPHOID IMMUNIZATION

To the Editor:—Kindly advise our local civil defense council as to generalized typhoid inoculations among civilians. It is common knowledge that, throughout the South, typhoid is pandemic and primitive conditions exist. In these areas many army camps are located. While it is true that all army men are inoculated against the typhoid group, is there any possibility of these men being carriers while on furlough at home here in the North? Does passive inoculation prevent carriers?

O. L. Murphy, M.D., Simsbury, Conn.

ANSWER.—General immunization to typhoid of a civilian population living in a modern community is not worth while; the necessary effort would be more profitably expended in other directions. It is the difficulty of maintaining adequate sanitary facilities for an army in the field that gives universal immunization of troops its value.

The carrier rate is directly and intimately related to the prevalence of clinical typhoid; present evidence strongly supports the belief that the chronic carrier almost always has a history of clinical typhoid and it is seldom if ever possible to rule out a previous infection completely. Since compulsory immunization was instituted, the carrier rate in the Army has been dependent on prior experience of the men with typhoid and is estimated (Dunham: Army Medical Bulletin No. 23, 1930) to be less than 1 per thousand; a conservative estimate of the carrier rate in the civilian population is 2 to 4 per thousand. Since 70 to 80 per cent of chronic carriers are women, it would require a typhoid rate in the army camp four or five times that of the home community to raise the carrier rate among the troops to the level prevailing in the home community. In the absence of such prevalence it is unlikely that the carrier rate in the civilian population is augmented by the return of men on furlough.

Typhoid antiserum is almost completely lacking in therapeutic value; hence its administration probably does not affect the incidence of the chronic carrier state to a significant degree. There is not sufficient information available to answer the questions of (a) the effect of prior immunization on the chronic carrier rate in recovered patients and (b) the relative frequency of ambulatory typhoid in immunized and nonimmunized groups. In the latter case the disease would have to be almost completely lacking in symptoms to escape detection in the Army.

TOXICITY OF MAGNESIUM

To the Editor:—A patient is now working in an atmosphere of magnesium powder. I have been unable to find anything as to its possible harmful effects. If it is harmful, would you kindly advise as to the best methods for its control?

Leo Hymovitch, M.D., Stamford, Conn.

ANSWER.—Compared with arsenic or lead, the toxicity of magnesium is low; yet three types of injury may be recognized. The first of these is magnesium metal fume fever, a condition similar to the well known brass founders' chills. This disorder follows exposure to recently produced magnesium oxide and may be expected when the magnesium is in molten form. The literature furnishes extensive descriptions of the disorder.

Secondly, in *Light Metals* for May 1941 there are descriptions of peculiar cutaneous injuries caused by implanted particles of light metals. It is there stated that:

Injuries caused by light metals tend to pursue a course characteristically different, and more severe, than those resulting from the heavy metals. The examination of 5,000 instances of such injury has enabled the investigators to establish the fact that two well defined types exist.

In the first, a visible particle of metal is found. If the injury is not treated, there ensues, in two to three days, a rapid and progressive inflammation of the site and of the lymphatic system. Vacuole formation occurs in the tissues as a result of hydrogen formation consequent on chemical reaction between the metal and the fluids in the tissues.

In the second type of injury the causative agent is metal dust, which enters a wound resulting, probably, from some other accident. The wound heals rapidly, but a painful granulomatous infiltration, which may persist for months, occurs. Subsequently these suddenly develop acute symptoms of inflammation, as in the first type of injury. Vacuole formation, however, does not occur. Instead, granulomatous cells and eosinophils, together, at times, with giant cells, are found.

A third form, and less well established, represents a spastic gastroenteritis characterized by abdominal pain, a sensation of pressure, loss of appetite, constipation and loss of weight, which may be accompanied by a cystitis. While this may be caused by inhalation of magnesium oxide, it has been produced by the ingestion of 4 Gm. of finely divided metallic magnesium over a period of forty-four days. The literature describing this third type recognizes the possibility that traces of manganese, copper, silicon and aluminum, along with the major constituent, magnesium, may have contributed to this disorder. The chief practical danger from magnesium centers about its ready inflammability and explosibility when in the form of fine dust. Its danger is increased through the presence of oils. The necessary personal protection against flame injuries is likely to assure practical protection against disease states with the exception of injury to the skin, which apparently may be produced by single minute particles. Protection calls for the wearing of flame proof clothing, which should be kept free from grease and oil. The surface of such clothing should be smooth and tightly woven to prevent the entry of sharp particles. In machining, large quantities of cooling agents should be employed to eliminate explosion reactions, and most of all there should be provided adequate dust exhausting facilities. In the presence of fire, obviously water or other liquid extinguishers are not suited and instead resort should be had to sand, talc, iron shavings or asbestos mats for smothering purposes. Lastly, it is noted that in plants handling large quantities of magnesium, explosion walls and other special features related to fires and explosions should be introduced.

IS POLAR BEAR LIVER POISONOUS?

To the Editor:—I have twice been told by arctic explorers that polar bear liver is poisonous. Any information that you can give me as to the accuracy of this statement and as to the nature of the poison contained, if there is one, will be greatly appreciated.

W. Osler Abbott, M.D., Philadelphia.

ANSWER.—There is a lack of conclusive evidence and a difference of opinion regarding the toxicity of polar bear liver and of the livers of other arctic animals. Some explorers have stated that the livers of polar bears, seals and Eskimo dogs are toxic, and three of these explorers are quoted in an article by H. Kohl (*Ztschr. f. Fleisch u. Milchhyg.* 40:45, 1929; *Bull. Hyg.* 5:126, 1930).

August and Marie Krogh in their "Studies of the Diet and Metabolism of Eskimos Undertaken in 1908 on an Expedition to Greenland" (*Meddelser om Gronland* 51:1, 1915) state that the livers of polar bears and of one species of seal (*Phoca barbata*) are rejected by Eskimos and their dogs because of their poisonous qualities.

Stefansson in his book "The Friendly Arctic" (New York, Macmillan Company, 1921) states that he has eaten polar bear liver many times without any ill effect but has observed others who complained of severe headaches and nausea after such a meal. He claims, as do many other explorers, that seal liver is a delicacy relished by the whalers as well as the Eskimos and is in no way poisonous.

There is an interesting report in Danish by J. Lindhard (*Hospitalstidende* 3:338, 1910) regarding the toxic effect of well cooked polar bear liver on 19 men on a Danish expedition to Greenland in 1907. He reports that within five to six hours after the ingestion of the liver the subjects developed vertigo and an uncontrollable desire to sleep. This was followed by severe and throbbing headaches in all 19 men. The temperature remained normal or slightly subnormal. All complained of a bad taste in the mouth, and ten showed scaling of the skin around the mouth. Some became nauseated and vomited, but the author stated that only 1 subject was severely affected in this way. Three showed tonic and clonic convulsions. In 2 cases, convulsions were limited to the lower extremities, but in the third they spread to the muscles of the trunk and shoulders. Symptoms did not entirely disappear until six days after the ingestion of the liver.

CORNEAL OPACITIES IN CHILDREN IN ALASKA

To the Editor:—I am writing for an outline of a plan for "the investigation of the causes and prevention of corneal opacities." I have made inquiry among many physicians on the incidence of corneal opacities among children living in Alaska, and without exception they state that they believe it to be many times greater than the incidence in a like group in the States. Although the population of the Territory is approximately equally divided as to whites and natives, the incidence of opacities is much greater among the natives. The most common suggestions as to the cause are avitaminosis, tuberculosis and physical trauma. I know that the incidence of tuberculosis in Alaska is many times greater than the incidence in the States. I suspect that a large percentage of the population in the Territory is not getting an adequate diet. Syphilis is probably not more prevalent than it is in the States. The problem was forcefully brought to my attention by the recent visit of an ophthalmologist to Nome. Of 89 children examined, 26 showed opacities of the cornea. The Division of Maternal and Child Health is carrying on a vision conservation program, which consists largely in the examination of preschool and school children by qualified ophthalmologists and the purchase of glasses for those who will be benefited by their use. At present there are three physicians in the Territory who confine their practice to eye, ear, nose and throat work. Children with opacities can be referred to these physicians. Approximately one third of the population of the Territory lives in Southeastern Alaska. It is likely that enough material can be found in this area alone to carry on a worthwhile investigation; and one of the ophthalmologists resides in Juneau. The Territorial Department of Health has laboratories in Juneau and Anchorage, both of which are adequately equipped and staffed to carry on bacteriologic and serologic investigations.

W. S. Ramsey, M.D., Juneau, Alaska.

ANSWER.—Since there have been no reports on high incidences of any form of ectogenous infectious keratitis among children in Alaska, the corneal opacities observed most likely are due to (1) the tuberculous and other forms of phlyctenular disease or (2) vitamin A deficiency, with or without an ectogenous infectious agent.

The corneal scars resulting from these diseases are usually characteristic in appearance and can be distinguished from scars due to trauma or infectious ectogenous keratitis. An inquiry into the clinical appearance of the corneal scars seen by the three ophthalmologists in Alaska may be expected to throw a great deal of light on the question of the cause of the scars.

The next logical step would be a systematic search, in those children with corneal scars, for ocular (xerosis of the conjunctiva) and cutaneous (follicular hyperkeratosis) signs of vitamin A deficiency and a study of the cutaneous sensitivity to tuberculin. These data would give valuable clues with regard to the prevention of keratitis in children. If vitamin A deficiency or high cutaneous sensitivity to tuberculin is found to be uncommon among children with corneal scars, one would have to think of other keratitis-producing agents, which could probably be identified by bacteriologic examination of smears from the conjunctiva or scrapings from the cornea during the acute phases of the keratitis. The whole problem is of great practical importance, since in all probability the majority of the keratitides are preventable.

POSTCOITAL HEADACHE

To the Editor:—A man aged 33 is subject to headaches which appear regularly twenty-four to forty-eight hours after coitus, with the definite sequence of a warning of heaviness in the head (frontal) for four to six hours and then localization of pain in the right eye and temple, accompanied by slight nausea. During childhood, when he practiced masturbation, he also suffered from headaches of the same type, only localized in the left eye, and no cause could be discovered by numerous physicians. Relief is sometimes obtained by acetylsalicylic acid or coffee, but only if taken early in the attack; if the attack is advanced, only long sleep will clear the headache. Various possibilities have been excluded: eye examination revealed no abnormalities, blood pressure was within normal limits, there was an absence of neuroathenic stigmas. All these gave no approach to the possible cause. Might there be a definite connection between the headaches and coitus? Two other circumstances may bring out headache, although not regularly. They are exposure to wind, sun or air and arising from bed after too long a sleep. M.D., New York.

ANSWER.—The case described has many stigmas of a psychogenic headache. It would be thoroughly worth while to investigate this angle of the situation in the greatest detail. It would be unwise to attempt any such therapy except under expert supervision, as it is obvious that the pathologic condition lies primarily in the sexual sphere.

The parasympathetic phenomena associated with coitus might readily be accompanied by vasodilator phenomena. Such vasodilatation is probably the cause of headaches of various types. On the other hand, it is well known that unsatisfactory sexual relations are often followed by vascular engorgement which may be cranial, abdominal or elsewhere and these in themselves may be psychologic precipitating factors.

Relief by coffee suggests that the type of headache is somewhat similar to a post lumbar puncture headache or to the more frequently encountered headaches of fatigue and emotional

disturbance. In the physiologic line it would be well to investigate the postural relations of blood pressure. The best therapeutic result probably would be obtained from psychologic investigations.

POSSIBLE ACUTE AGRANULOCYTOSIS

To the Editor:—The Encyclopedia of Medicine, Surgery and Specialties, volume 1, page 279, on the treatment of agranulocytosis advocates adenine sulfate intravenously. Where can I get the drug? Does it ever give severe reactions when used? What other treatment would you suggest? The leukocytes number 1,600, the erythrocytes 2,170,000. The hemoglobin is 50. The patient has had a gastric ulcer with hemorrhage the last two years; the ulcer at present is healed. Pentnucleotide has also been advocated.

J. L. Woldner, M.D., Loveland, Colo.

ANSWER.—Treatment of acute agranulocytosis is not satisfactory. Adenine sulfate is difficult to obtain and probably can be had only for experimental purposes. Reactions do occur when it is used intravenously. Pentnucleotide can be obtained on the market and is usually given intramuscularly in a dose of 10 cc. four times daily. Reactions can be largely prevented by the liberal use of atropine sulfate. The efficacy of these drugs is open to question, but pentnucleotide may be recommended for trial.

From the blood picture presented, the diagnosis of acute agranulocytosis should be seriously questioned. Severe anemia is not characteristic of this disease. An aleukemic leukemia or metastatic involvement of the bone marrow should be seriously considered. A sternal biopsy might settle this point.

CONGENITAL BLINDNESS FROM FAILURE OF CORNEAL DEVELOPMENT

To the Editor:—Two months ago my sister gave birth to an infant which was congenitally blind as the result of failure of development of the cornea. Consultation with an ophthalmologist discloses little or no hope of cure. The infant has no other anomalies. The parents are entirely negative to examinations, including laboratory tests. The familial history is negative. I am interested in the prognosis and advice regarding education and training of a blind infant. M.D.

ANSWER.—Only 1 case of such congenital failure of development has been seen in a long ophthalmologic experience. This pear shaped cornea had become much more circular twelve years later. As far as treatment is concerned, the child should be placed in a school for the blind as early as one of the twenty-six state and private schools for the blind will accept it. The age when the child is taken and the emphasis which particular schools place on work for the youngest children will naturally vary.

GYNECOMASTIA AND TESTOSTERONE

To the Editor:—Would testosterone propionate help gynecomastia in an otherwise well developed man aged 20 years? The beard and the penis are slightly below normal, but his figure is distinctly masculine.

S. C. Mason, Menominee, Mich.

ANSWER.—The simplest procedure in the treatment of such a patient is to remove the breasts if they are large, as there is no assurance that any effect of testosterone obtained would be permanent. The effect of testosterone in such patients is unsettled. Wernicke has reported recession of gynecomastia with hypoplasia of the testes in a person of this type. In other subjects perhaps lacking hypoplastic testes there has been no improvement. It is suggested that the state of the testes be carefully studied and the semen be examined. If spermatozoa are abundant and normal, treatment with testosterone propionate may temporarily suppress spermatogenesis. Testosterone propionate, in doses of 25 mg. given three to four times weekly, may be used for three to four months; the results would furnish a welcome addition to knowledge of this anomaly.

THERAPY OF MENINGITIS

To the Editor:—In reference to Dr. Hoynes' article on the therapy of meningitis in the Dec. 6, 1941 issue of the Journal: While I was resident in medicine at Miami Valley Hospital, Dayton, Ohio, I treated 5 cases of meningococcal meningitis with sodium sulfathiazole, having previously good results in all cases. I used the drug because of its good results in gonococcal infections and because of the family linkage of the gonococcus and the meningococcus. I used an initial dose of 10 Gm. gamacoccus and continued with the same drug in powder form, 33 intravenously and continued with the same drug in powder form, 33 intravenously (2 Gm.) every four hours the first day and corresponding reduction until the clinical course was satisfactory. The spinal fluid level in all cases ranged from 70 to 90 per cent of blood levels taken simultaneously. The spinal fluid was cleared on the average in forty-eight hours. Few toxic effects resulted. Adjuvantive transfusions and parenteral fluids were used as indicated. My experience, though limited, substantially bears out Dr. Hoynes' assertion that sulfathiazole as the sodium salt does pass into the spinal fluid.

THE INFLUENCE OF ANDROGENIC AND ESTROGENIC SUBSTANCES ON THE SERUM CALCIUM

IN CASES OF SKELETAL METASTASES FROM
MAMMARY CANCER

JOSEPH H. FARROW, M.D.
AND

HELEN Q. WOODARD, PH.D.
NEW YORK

The favorable reports¹ of retardation of the growth of skeletal metastases from breast cancer following castration of premenopausal women suggested that similar results might be produced by injections of testosterone propionate. This clinical experiment was begun more than two years ago. Thirty-three patients with skeletal metastases from breast cancer were given doses of from 5 to 25 mg. of testosterone propionate in sesame oil one to three times a week for totals of ten to twelve doses. About one half of the patients obtained relief from pain, but there was neither clinical nor roentgenographic evidence of control of the disease in any patient. Because relief from pain had been obtained, 3 patients were subjected to more intensive therapy. The unexpected hypercalcemia and apparently increased growth of the metastases which followed massive doses of testosterone propionate and subsequent smaller doses of estrone are the main subjects of this report.

REVIEW OF THE LITERATURE

In reviewing the literature one is impressed by the reports of unusual changes occurring in the skeletal system in association with breast cancer. Paget,² after referring to the work of Török and Wittelshöfer, added 6 cases of "fragility of the bone" in patients with cancer of the breast. Spontaneous fractures occurred in such areas of bone absorption and yet no evidence of metastatic cancer could be found. He expressed the opinion that "a general degeneration of the bones sometimes occurs in cases of cancer of the breast, yet without any distinct deposit of cancer in them," and later added that he believed that the bones suffered

in a special way. Sheild³ called attention to Paget's observations and reported similar ones. Williams,⁴ however, was inclined to attribute these manifestations to cachexia and disuse. Klemperer⁵ made extensive postmortem studies on a patient aged 46 with widespread skeletal metastases from breast cancer. He was impressed by the status of the uninvolved areas and found that the changes resembled osteomalacia; in fact, he suggested the use of the term "osteomalacia carcinomatosa." Histologic studies of the parathyroids revealed hyperplasia which he interpreted as a part of the defense mechanism of the body. A similar case of parathyroid hyperplasia is recorded by Delannoy, Driessens and Demarez.⁶ Their patient, aged 45, had extensive skeletal metastases from a breast cancer. A mass was removed from the thyroid region and on histologic study proved to be hyperplasia of a parathyroid gland. After the operation there was a slight elevation of the blood calcium from 11.6 mg. to 14.2 mg. per hundred cubic centimeters. They were particularly impressed by the considerable relief of pain and general improvement in the patient following the operation.

Mason and Warren⁷ reported a case of extensive osteolytic metastases with hypercalcemia (17.5 mg. per hundred cubic centimeters) and a metastatic mass of adenocarcinoma in the right parathyroid region. Removal of this caused no appreciable change in the serum calcium level. Their patient, aged 46, had previously had a simple mastectomy for what was said to be a cancer of the breast. Egorville⁸ recorded a case of breast cancer with osseous metastases and a serum calcium level of 18.1 mg. per hundred cubic centimeters. This patient, aged 30, had as her first symptom a persistent pain in the back, beginning in the sixth month of pregnancy. Postmortem studies revealed no parathyroid hyperplasia, but extensive deposits of calcium were found in the lungs and kidneys. He concluded that this was an instance of "metastatic calcification" such as described by Virchow and said to occur in many cases of widespread bone absorption and in inflammatory and chronic diseases as well as in parathyroid disturbances and primary diseases of the bone. The Gutmans and Tyson,⁹ in studying

the blood chemistry of primary and secondary neoplasms of bone, listed the serum calcium values in 13 cases of metastatic mammary cancer. The values ranged from 9.9 mg. to 13.1 mg. per hundred cubic centimeters. The three highest determinations were made on patients aged 35, 40 and 41 respectively.

The last four reports strongly suggest a systemic factor which materially contributes to the presence and

sible that, prior to the menopause, ovarian hormones may have contributed to the activity of the bone metastases. We have no adequate explanation for the apparent activity in the postmenopausal group.

From clinical observations we have been impressed by two things: first, in the premenopausal group osseous metastases usually occur early and are apt to precede the involvement of distant viscera; second, in the postmenopausal group bone metastases occur relatively late and may follow or be associated with visceral metastases. It seems that in the natural course of events skeletal metastases may be delayed but not prevented by the endocrine disturbances of the menopause.

REPORT OF CASES

CASE 1.—History.—L. L., a white woman aged 26, admitted to Memorial Hospital Oct. 21, 1939, complained chiefly of a severe pain in the thoracic spine of two and a half months' duration. Prior to the onset of the present illness she had enjoyed good health. The menses had appeared at 13 years and were regular, with the flow lasting about six days. She had never experienced any premenstrual symptoms in the breasts.

The patient became aware of the present illness, which began insidiously and without symptoms, one year previously when she accidentally noticed a small growth in the right breast. This had persisted without noticeable change except for slight pain during the past two weeks. The patient thought that the pains in her back had been caused by a sprain, but they had persisted and gradually extended to the pelvis and both thighs. For this reason she had been partially incapacitated and had remained in bed during most of the past month. There had been a loss of weight of 17 pounds (7.7 Kg.) but no associated gastrointestinal, respiratory or urinary disturbances.

Physical Examination.—The patient was well developed but undernourished and had a noticeable overgrowth of hair on the extremities. Positive physical manifestations were as follows: The contour of the right breast was altered by a mound-like swelling located in the upper central portion of the breast. This tumor measured 4 by 3.5 by 2.5 cm. and was attached

Chart 1.—An analysis of 200 instances of skeletal metastases occurring (broken line) in 1,380 cases of breast cancer (solid line) showing a definite decrease in the frequency of bone metastases during the years of the normal menopause.

activity of skeletal metastases from breast cancer. We believe that the ages of these patients are significant in that they fall within the range of ovarian activity. This view seems to be supported by observations on the effect of the menopause on skeletal metastases.

EFFECT OF THE MENOPAUSE ON SKELETAL METASTASES

It is generally agreed that an artificial menopause following ovarian irradiation will temporarily retard the activity of skeletal metastases in certain cases of breast cancer. This is demonstrated by the relief from pain, apparent reduction in the rate of growth and occasional calcification of osteolytic lesions. These manifestations of clinical improvement appear at the onset of the menopause and continue mainly during the period of hormone imbalance and readjustment which follows the castration. After a variable time, ranging from several months to one or two years, there is evidence of reactivation of disease. From limited clinical observations we are of the opinion that the renewed activity coincides with a decline of the menopausal symptoms.

While this sequence of events is more clearly seen at the time of artificial menopause, it may to some extent be noted during the natural menopause. An evaluation of any effect of a natural menopause is rendered difficult because of variations in time and duration of the menopause in different patients. Furthermore, authorities differ as to what constitutes the onset of the menopause. Many believe that the hormonal disturbances may begin several years before and continue many years after the cessation of menstruation. Hence in analyzing a large series of cases any effects observed may be expected to involve a period of several years.

We have studied the age incidence in 200 instances of skeletal metastases occurring in 1,380 cases of breast cancer. In chart 1 the percentage of cases of mammary cancer in which bone metastases developed has been determined for each five year period. One notices immediately a decrease in the percentage of skeletal metastases during the years of the natural menopause, while a relatively high percentage occurs just before and after the years covering this event. It seems pos-

Chart 2.—Summary of the calcium (Ca), phosphorus (P) and phosphatase (P-ase) levels in the serum and determinations of the urinary calcium (Ca) in case 1. Serum calcium and phosphorus are given in milligrams per hundred cubic centimeters; serum phosphatase is given in Bodan'sky units per hundred cubic centimeters and urinary calcium in grams excreted per day. Note the sharp rise of the serum calcium following the injections of both testosterone propionate (T) and estrone (E).

to the skin but moved slightly over the chest wall. In the midaxilla there was a metastatic node 1 cm. in diameter. Examination of the back revealed no gross abnormalities except a definite rigidity of the spine and tenderness over the third dorsal vertebra. Passive motion of the hip joint disclosed no evidence of limitation, but walking was extremely difficult because of pain which originated in the sacroiliac region and

radiated to the knees. Blood smears showed slight secondary anemia; urinalysis was negative. Roentgenographic studies demonstrated osteolytic lesions in the ribs, spine, cranium and pelvic bones. A roentgenogram of the chest was negative. Aspiration biopsy of the breast tumor was reported "cancer."

Treatment.—Owing to the widespread metastases and noticeably favorable response to small doses of testosterone propionate by other patients, it was decided to treat this patient by endocrine therapy alone. She was admitted to the hospital and on November 7 (*T*, chart 2) 25 mg. of testosterone propionate in 1 cc. of sesame oil was injected into the gluteal muscle. During the following six consecutive days the dose was increased to 75 mg. daily, making a total of 475 mg. in seven days. Because of certain laboratory studies and menopausal symptoms she was given, six weeks later,

Chart 3.—Summary of blood and urinary determinations in case 2. Elevation of the phosphatase indicates an attempt at bone regeneration. The date of irradiation is noted by X. Other symbols are explained in legend for chart 2.

2 mg. of estrone (*E*) in oil intramuscularly and, after an interval of five days, an additional 4 mg. On Jan. 2, 1940, nine days later, a second series of testosterone (*T*) injections was started, 50 mg. daily being given for a total of seven doses.

Clinical Observations.—On the sixth day of the initial course of injections the patient began complaining of severe headaches, lack of appetite and a sharp increase of pain in the back and pelvis. These symptoms continued the next day and were accompanied by nausea and vomiting. The patient appeared stuporous, and it was thought that she was suffering from cerebral metastases. The symptoms persisted, and for three days the patient took only limited amounts of fluids, supplemented by infusions of dextrose and saline solution. At this time blood studies revealed a calcium determination of 18.9 mg. The testosterone injections were discontinued and the symptoms gradually subsided. It is significant that a similar syndrome followed two days after the administration of the estrone and likewise after the second series of testosterone propionate injections. Determinations of the calcium, phosphorus and phosphatase during this time are shown in chart 2.

The patient did not menstruate at any time while under observation. Coincidentally with the symptoms of hypercalcemia she complained of feeling flushed about the head, neck and upper part of the thorax. These flushes appeared to simulate those associated with the menopause. The sharpness and frequency of the flushes decreased, but they did not entirely disappear when the serum calcium returned to normal levels. Pains in the back and pelvis persisted during the course of the injections. There was a slight increase in the size of the breast tumor. Roentgen studies demonstrated a striking increase in the extent of the osteolytic metastases of the ribs, spine and pelvic bones. In general, the clinical course of this patient was one of progressively failing health owing to widespread and uncontrolled metastatic disease. She continued to lose weight, became cachectic and anemic and died January 17.

Autopsy.—This revealed a carcinoma of the right breast with involvement of the adjacent axillary lymph nodes. The narrow cavities of the ribs, sternum, vertebrae and pelvic bones were solidly filled with carcinomatous tissue. Small foci of tumor cells were found in the ovaries, the right lobe of the

thyroid and the spleen. The lungs were not involved grossly, but microscopic examination revealed tumor cells in the bronchial lymphatics.

Histologic examination revealed an infiltrating duct carcinoma grade 3 in the breast metastatic to the regions previously described. Sections of the parathyroids showed that the normal arrangement of the cellular structure had been completely altered. There was evidence of a complex hyperplasia. This was diffuse throughout and involved principally the oxyphilous cells and the clear cells which are intermediate between the chief and the water clear (wasserhelle) types. The cellular proliferation did not form true acini but was arranged about globules of mucoid material, apparently resulting from complete mucoid degeneration of one or more cells.

Additional microscopic studies were of some interest. In the normal breast there was a definite fibrosis with almost complete disappearance of the breast epithelium. Few acini remained, and these were lined by atrophic and degenerating epithelial cells. The whole picture was one of advanced sclerotic involution commonly seen but to a less severe degree in senile women. Sections of the ovaries revealed almost complete absence of oocytes with moderate proliferation of the stroma.

CASE 2.—B. V., a woman aged 37, applied for admission to Memorial Hospital Jan. 15, 1940 with a history of having had a left radical mastectomy in another institution during November 1938. The pathologic report was infiltrating duct carcinoma grade 2. Following the operation she had remained well until one month prior to her initial visit. At that time she began having persistent pains in the lower part of the back. Associated with the present illness the patient had a feeling of general malaise, loss of appetite and a slight decrease in weight. Her menses were regular though scant.

Physical Examination.—The patient was fairly well developed and appeared chronically ill. The heart, lungs and abdomen were essentially normal. Locally there was a well healed scar on the left side from a radical mastectomy, without evidence of local recurrence or regional metastatic disease. Slight tenderness was noted over the upper part of the lumbar spine.

Roentgenographic studies revealed a destructive metastatic process involving the left innominate bone and the body of

Chart 4.—Summary of blood and urinary determinations in case 3. Symbols are explained in legends for charts 2 and 3.

the first lumbar vertebra. A roentgenogram of the chest was negative. A complete blood count revealed slight secondary anemia.

Treatment.—The patient was admitted to the hospital January 22. One week later (*T*, chart 3) injections of testosterone propionate were started. During the following eight days she received a total of 400 mg., given at the rate of 25 mg. twice a day. Because of symptoms of hypercalcemia the injections were discontinued.

The metastatic lesions became more painful and on February 26 (X) general body irradiation totaling 30 roentgens was given. On March 4, 2 mg. of estrone was given intramuscularly. This was repeated sixteen days later. All other treatment was symptomatic and for the most part consisted of infusions to replace fluids lost by vomiting. On one occasion a blood transfusion was given because of the secondary anemia.

Clinical Course.—Chart 3 shows the blood studies on admission and summarizes the changes which occurred during the course of treatment. The initial serum calcium was 11.6 mg. On the third day after the initial dose of testosterone propionate the patient complained of slight nausea and headache. The nausea became progressively worse and later was followed by vomiting. The serum calcium determination on the sixth day of treatment showed an increase to 12.4 mg. This increase continued until the serum calcium level was reported 15.4 mg. on the fifth day after the injections had been discontinued. Associated with the elevation of the blood calcium the patient began having hot flushes similar to those described in case 1. These symptoms subsided but did not disappear when the serum calcium returned to a normal level. A similar syndrome followed the injection of the estrone. During and after the course of treatment the patient obtained no relief from pain. An enlarged liver and signs of pulmonary metastases developed. Roentgen studies revealed a rapid increase in the size of preexisting foci of skeletal metastases as well as the development of additional foci. The patient left the hospital for terminal care in another institution and died in December. Permission for autopsy was not obtained.

CASE 3.—S. S., a woman aged 60, admitted to Memorial Hospital Jan. 13, 1940, gave a history of having had a radical mastectomy on the right side in July 1937. Following this her health had remained good until eight months prior to the date of admission, at which time she began to have pains in the left thigh. Roentgenographic examination at that time showed metastases in the left femur and pelvic bones. These were treated by roentgen therapy but apparently there was only slight relief. Recently pains developed in the right knee, left shoulder and right clavicle. There had been some loss of weight but no other associated systemic disturbances. For one year prior to her operation menstruation had been irregular but, following the operation, she had had on one occasion a scant menstrual flow. Apparently the menopause had not been established at the age of 58.

Physical Examination.—The patient appeared undernourished and chronically ill. Physical manifestations related to the present illness were a recurrent tumor 2 by 2 by 1 cm. located at the junction of the right clavicle and sternum, and a considerable swelling of the midportion of the right thigh. Radiographic studies demonstrated widespread osteolytic metastases involving the vertebrae, ribs, skull, sternum, left scapula, pelvic bones and both femurs. Roentgenograms of the chest revealed questionable metastases in the left lung. A blood count showed only slight secondary anemia.

Treatment.—Beginning on January 28 (T, chart 4), the patient was given two 25 mg. ampules of testosterone propionate daily for ten days. Because of continued pain, general body irradiation totaling 30 roentgens was administered on February 26 (X). This was followed by 2 mg. of estrone in oil on March 4 (E). Other treatment was mainly symptomatic and included treatment of the local recurrence with the radium pack and high voltage roentgen therapy to the cervical vertebrae.

Clinical Course.—The blood chemistry and urine studies are summarized in chart 4. It is interesting to note that, in spite of the widespread skeletal lesions, the initial serum calcium determination was well within normal limits. Following the elevation of the blood calcium a similar syndrome but less severe than those described in the two previous cases developed. Hot flushes were experienced on the seventh day of injections. Nausea was persistent but no vomiting occurred. A pathologic fracture of the right humerus was sustained on

March 19. Other areas of skeletal metastases increased in size and later a fracture of the right clavicle occurred.

After several weeks of progressively failing health the patient died on April 27.

Autopsy.—This revealed generalized skeletal metastases to the ribs, sternum, vertebrae, ilium, pubis, both clavicles, both humeri, the left femur and the sacrum. Other metastatic foci were found in the lungs, peritoneum, para-aortic, mesenteric and omental lymph nodes as well as the liver and pericardium. Histologic examination confirmed the gross examination and revealed an additional focus in one parathyroid.

COMMENT ON CHEMICAL FINDINGS

Summarizing the blood chemical findings in these 3 cases of bone metastases, we see that after each course of testosterone propionate there was a sharp rise in serum calcium which persisted for a week or ten days after the cessation of therapy. In 2 (cases 1 and 2) there was a similar rise after the administration of estrone. In 2 (cases 2 and 3) a rise in serum phosphatase was found from two to three weeks after the injections of testosterone. In all 3 cases the serum inorganic phosphorus was occasionally or persistently above normal. The daily urinary excretion of calcium tended to follow the blood levels rather closely.

It is obvious from the results of the clinical, chemical and roentgenographic examinations that the administration of testosterone propionate was followed by an increase in bone absorption associated with flooding of the circulation with calcium and phosphorus. In 2 of the 3 there was an attempt at bone repair by increased phosphatase formation.

The question now arises whether the effect of testosterone propionate on bone is primary or secondary. There is a theoretical possibility that a primary metabolic defect might exist in patients with breast carcinoma which would result in the transformation of sex hormones into a sterol which would directly affect calcium and phosphorus metabolism. This substance, by promoting withdrawal of calcium and phosphorus from the bones, might render them more susceptible to metastatic invasion. Such a hypothesis would explain the strong tendency of breast carcinoma to form skeletal metastases, particularly in the premenopausal and postmenopausal group. On the other hand, testosterone propionate, instead of preparing the ground for the establishment of metastases to bone, may simply stimulate the metabolic activity of metastases already established, with secondary increase in the rate of bone destruction.

One method of deciding which of these two hypotheses is correct is to study the effect of sex hormones on the serum calcium and phosphorus of patients with carcinoma of the breast which has not yet metastasized to bone. This has been done in 2 cases. One patient received 600 mg. of testosterone in twelve doses over a period of three weeks. Another patient, who had carcinoma of the rectum as well as carcinoma of the breast, received 5 mg. of estrone in three doses and one 10 mg. dose of progesterone during two weeks. The serum calcium and phosphorus were within normal limits throughout, and no significant changes were observed during hormone therapy. The negative results in these 2 cases suggest that the hormones used have no effect on the calcium and phosphorus metabolism of patients with carcinoma of the breast which has not yet metastasized to bone.

In a previous publication one of us¹⁰ observed that in patients with carcinoma of the breast metastatic to bone who had not received hormone therapy the serum inorganic phosphorus tended to be slightly elevated and the serum calcium to show a rather wide variation. As this observation has an obvious bearing on the subject of the present paper, we have extended our previous studies to include serum calcium determinations on (a) 45 normal persons, (b) 49 patients with osteitis deformans, (c) 52 patients (48 women and 4 men) with carcinoma of the breast metastatic to bone, (d) 26 women with carcinoma of the breast without bone involvement, (e) 78 men with carcinoma metastatic to bone and originating in organs other than the breast. In about half of the last group the primary growth was in the prostate and the metastases were predominantly osteoplastic. The results are sum-

Summary of Serum Calcium Readings

Diagnosis	Number of Cases	Average Serum Calcium, Mg. per 100 Cc.	Per Cent of Total Readings Between					13.0 Mg. per 100 Cc.
			8.0-8.9 Mg. per 100 Cc.	9.0-9.9 Mg. per 100 Cc.	10.0-10.9 Mg. per 100 Cc.	11.0-11.9 Mg. per 100 Cc.	12.0-12.9 Mg. per 100 Cc.	
a Normals.....	45	10.7	0	2.2	75.0	15.5	6.7	0

d Carcinoma of breast without bone metastases	26	10.8	0	3.9	61.5	26.9	7.7	0
e Males with carcinoma and metastases to bone	78	10.5	2.5	9.0	65.4	21.8	1.3	0

marized in the accompanying table. The differences between the average serum calcium values for the different groups are too small to be significant. It is suggestive, however, that the lowest average values are for groups b and c, in which the bone changes were chiefly productive, while the highest average is for group e, in which the lesions were chiefly destructive. If, instead of averages, one considers distributions, it is found that there are significant differences between the groups. It is well known that in normal persons the calcium content of the serum is constant. In our series more than three fourths of the readings were between 10 and 10.9 mg. per hundred cubic centimeters. Only a single determination was below 10 mg. Of the total, 22.2 per cent were 11 mg. or above. A much wider range was encountered in the three groups with bone disease. It is particularly striking that of the patients with carcinoma of the breast metastatic to bone 40.4 per cent had serum calcium readings of 11 mg. or above. In contrast to this, in the group of patients with carcinoma of the breast not involving bone the deviations from normal were small. We conclude from these figures that the mechanism for regulating serum calcium levels is disturbed in osteitis

deformans and in several types of metastatic disease of the bone. The changes are most noticeable in the presence of skeletal metastases from breast carcinoma but are not specific for this condition. There is no clear-cut evidence that they appear prior to the onset of bone involvement as they would if due to pre-existing endocrine abnormality.

Finally we may mention a case reported to us through the courtesy of Dr. Norman Treves of this hospital. The patient was a girl aged 14 years who had a neurocytoma which had caused widespread destructive bone lesions. The serum inorganic phosphorus was in the upper normal range and the serum calcium was noticeably elevated, fluctuating between 13.6 and 19.4 mg. per hundred cubic centimeters. At autopsy extensive disease of the bones and soft parts was found. The urinary tract was full of calcific deposits. The adrenals, thyroid and parathyroids were essentially normal, and only the serosa of the uterus and ovaries was involved. This patient's cancer did not originate in the breast and there was no evidence that it had had any direct effect on the sex or parathyroid hormones. It appears likely, therefore, that the high serum calcium was due simply to a flooding of the circulation with the products of osteolysis. Yet the blood chemical abnormalities closely parallel those which occur spontaneously in patients with carcinoma of the breast metastatic to bone or which may be produced in them by administration of sex hormones.

CONCLUSION

In 3 cases of carcinoma of the breast metastatic to bone injections of testosterone propionate were followed by a decided rise in the concentration of calcium in the serum and in the excretion of calcium in the urine. In 2 of these cases similar changes also followed injections of estrone. The chemical changes were accompanied by clinical and roentgenographic evidence of increased activity of the metastatic disease in the bones.

In 2 cases of carcinoma of the breast without skeletal metastases injections of testosterone, estrone or progesterone were not followed by significant changes in the serum calcium levels.

A study of 130 cases of cancer metastatic to bone showed numerous spontaneous disturbances in the serum calcium levels. The changes were most frequent when the breast was the site of the primary tumor but occurred also in the presence of skeletal metastases from cancer of other organs.

The ability of testosterone and estrone to cause hypercalcemia in patients with carcinoma of the breast metastatic to bone appears to be due to a stimulation by these hormones of the growth of the metastatic tumor. This in turn causes an acceleration in the rate of bone destruction accompanied by a flooding of the circulation by the products of osteolysis.

The evidence demonstrated here that testosterone in large doses exerts a stimulating rather than an inhibiting effect on the growth of metastatic mammary carcinoma obviously contraindicates its use in the treatment of this disease.

The reason why an androgenic substance stimulates a tumor of a female reproductive organ remains obscure and merits further study.

MANAGEMENT OF BURNS IN
CHILDRENAN ANALYTIC STUDY OF TWO HUNDRED
AND FIFTY CASESH. JERRY LAVENDER, M.D.
CINCINNATI

It is generally conceded that the systemic treatment and management of patients with a serious or extensive burn is just as important as the local therapy, if not more so. This is because much has been learned, especially during the past decade, through clearer concepts of supportive treatment. Although any recognized form of local therapy may be used, provided it is carried out properly, one may safely say that it is the systemic or supportive treatment that saves the patient or, to say the least, enhances the recovery.

The advocates of the various forms of local therapy should and in most cases do accept the foregoing statement as axiomatic; those who do not share in this view or are unwilling to accept it are not facing the facts presented to them after many years of evaluation. To laud a certain form of local therapy in a case of serious burn and to attribute the recovery to the local approach alone should cause one to accept the statement with a grain of salt.

It is not within the scope of this paper to discuss the importance of laboratory procedures in determining the status of the burned patient. However, it is only after the proper management and adequate amount of systemic or supportive treatment have been instituted to combat shock, toxemia and other complications that one has the right to evaluate the various forms of local therapy. I am fully cognizant of this point in presenting this paper, which deals only with local management.

It must be emphasized that there is a vast difference in the texture and thickness of the skin of adults from that of infants or young children. The cutaneous layers in the latter are not well developed; the stratum corneum and other layers of the epidermis are thin, and the corium, or true skin, not only shows a relative thinness but is poorly supported with connective and fatty tissues. As compared with adult skin, it offers a meager resistance to trauma or insult such as a burn. For this reason, heat of the intensity which produces a first or second degree burn in an adult will, in the majority of instances, produce a third degree burn in an infant or young child.

By third degree I mean involvement of the corium or deeper tissues and structures. With children, so often what appears to be a relatively superficial burn at first proves to be much deeper, even third degree, a few days or a week later.

This is especially true of burns caused by fire. One is impressed by the relative dryness and seared appearance of the skin of most patients burned by fire when they are seen shortly after the accident. This is because the intensity of the fire remains the same as long as it comes in contact with the integument and results in a rapid and deep cooking of the tissues. If the patient survives, after a week or ten days one sees or can

visualize for the first time the actual depth of involvement; at this time the tissues begin to slough and beginning restoration of the deeper structures takes place. Pyogenic infection, when present, is also more noticeable at this stage.

Scalds, on the other hand, are more superficial as a rule, and the burned areas show greater bullous formation, with more of inflammatory reaction. I therefore believe, and this is contrary to the general belief, that fire burns as a rule are deeper and more serious than scalds. The statistics presented in this article will, I think, support my contention.

In an analytic study of this question on 250 burned infants and children, I present what I believe to be some facts and statistics not previously recorded in similar fashion. I shall discuss the comparative results of the following methods: the use of crust formers or coagulants, the use of wet dressings with antiseptic solutions, the compression or closed method and the tubbing procedure. No case is included in which less than 10 per cent of the skin area was involved.

The series comprises 145 (58 per cent) white and 105 (42 per cent) Negro infants and children admitted to the Cincinnati General Hospital during the five years from Jan. 1, 1936 to Jan. 1, 1941. The ages ranged from 2 months to 12 years, and boys predominated (53 to 47 per cent). Of the patients, 13.2 per cent were 1 year of age or under, 50 per cent were 2 to 4 years, 18 per cent were 5 to 7 years and 18.8 per cent were 8 to 12 years.

Seventy (28 per cent) were burned by fire and 180 (72 per cent) were scalded. For the fire burns, open fire grates, explosions and matches were the chief causes (90 per cent); for the scalds, hot water and coffee topped the list (78 per cent).

Irrespective of the type of local therapy, the average period of hospitalization for the group with fire burns was fifty-five days (table 1). This included the cases in which grafting of skin was performed. The inclusion necessarily raised the average stay considerably, the average time prior to grafting being twenty-eight days. The average for the scald group was only eighteen days, or one third that for the fire group.

An analysis shows that 30 per cent of all the patients had some form of involvement of the leg, and these alone required an average stay of fifty-eight days. The patients with fire burns stayed ninety days, on the average, and those with scalds twenty-six days. Therefore, the patients with fire burns of the leg required three and a half times as much time as those with scalds of the leg. Again grafting played an important part in raising the average time in the hospital of the patients burned with fire, as forty-five days were consumed before the graft procedure. No other group of patients, considering the areas involved, required such a long hospitalization period.

The temperature curve (chart 1) shows that it required an average of six days for a normal level to be reached and maintained in the scald cases, while ten days were required in the fire cases, over half again as long. Also, a higher peak throughout was maintained in the fire cases. This is probably based on the fact, as previously stated, that the trauma sustained by fire was deeper and resulted in greater sloughing and infections.

Drs. E. A. Glicklich and A. B. Henningsen assisted in compiling the statistics.

From the Department of Dermatology, Pediatric Division, Cincinnati General Hospital.

Read before the Section on Pediatrics at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

Thirty-three (13.2 per cent) patients 1 year of age and under had an average stay in the hospital of but seventeen days. This is due to the fact that nearly all had scalds; areas and depths were not so great and, although the vast majority required general or supportive treatment, an adjustment was noted within a few days.

A different picture was noted in the 2 to 4 year group of 125 patients (50 per cent), in which an average stay of thirty-five days was required. In this group were noted most of the cases in which there was involvement of 25 per cent or more of the skin area and which presented the most serious problems.

In the 5 to 7 year group the 45 children had an average stay of thirty-four days, while the 47 children in the 8 to 12 year group had an average of thirty-three hospital days. In this analysis the shortest hospitalization periods are found at the two extremes of the age groups, the youngest and the oldest, with the longest period given to the children ranging from 2 to 4 years.

There is no doubt that delay in administering any form of therapy plays a role in increasing the hospital stay of these patients. The longer the interval between the accident and hospitalization the more serious the prognosis. Also, the earlier the proper aid, the less the infections encountered. Our records reveal that 18 per cent of all patients were admitted to the hospital within one hour after being burned, 40 per cent were admitted from one to two hours after being burned and 42 per cent were admitted after three or more hours had elapsed. Eighty per cent of the wounds of those admitted after a lapse of twelve or more hours either were infected or became infected shortly afterward, and the hospital stay was increased by several days. This emphasizes the importance of instituting not only supportive but also local therapy as early as possible and deals with the proper education of the public along these lines to get the burned victim hospitalized as soon as possible.

Secondary infection or contamination of wounds was twice as frequent in the burns in which home remedies and improper local applications had been used prior to hospitalization. Almost half (48 per cent) of all the patients were given some form of local therapy prior to admission.

Just to list some of the absurd applications, as found in my records, I mention oils of all kinds, lard in combination with soap, sulfur and butter, wash bluing, coal oil, soot and axle grease. It is well established that grease and oil, unless they have some strong antiseptic properties, pave the way for infections and are therefore a hindrance rather than beneficial, even though, when originally applied, the soothing effect may have seemed indicated.

WET DRESSINGS

Forty patients (16 per cent) were treated with continuous wet dressings after a thorough débridement of the bullae and loose tissue. Weak Burow's solution (not stronger than 1 part to 50 of physiologic solution of sodium chloride) or, if infected, Burow's bichloride solution was used in the majority of instances. Most of these patients presented involvement of the scalp, face or neck which, for obvious reasons, was not suitable for other types of therapy. If this procedure is followed,

soft cotton, muslin or linen cloth should be used and should replace gauze or any wide meshed covering in order to prevent, or hold to a minimum, the adherence of the dressing to the wound. As a rule, burns of the face and neck heal rather rapidly and this method should prove efficacious in the vast majority of cases provided care is exercised early to avoid contractures. Even scalp burns manifest rapid improvement if care is taken to shave the head and hold down secondary contaminants. Wet dressings are indicated also when the genitalia are involved and for superficial burns of other parts. In clean wounds, the dressings need not be changed oftener than every twelve to fifteen hours provided they are kept wet continuously. After a few days to a week one may change to a mild salve such as 5 per cent boric acid ointment or, if there is evidence of any secondary infection, to a 2 to 3 per cent ammo-

niated mercury ointment, or a combination of dilute Burow's solution and 1 per cent acetic acid solution will usually give the desired end result.

The average hospital stay of all patients who were treated with wet dressings was nineteen days; that for fire burns was twenty-four days and that for scalds fourteen days—ten days longer for the fire burns (table 1). This group reached its temperature peak on the second day (chart 2) and the normal range on the seventh day.

At this point something should be mentioned about débridements. I believe that all blisters should be opened and all the loose tissue removed as soon as possible. It is not enough merely to drain or aspirate the bullae; all burned areas should be denuded and cleaned off well into the normal surrounding tissue, dry gauze sponges being used to cleanse the field, and debris should not be picked off piecemeal with forceps. On completion of this procedure, if done properly, the whole area will be smooth, without any tabs or irregularities

visible at the edges of the wounds. This will prevent other bullae from forming hours later; the chances for infection are reduced and healing will take place more rapidly. Also, on completion of a thorough débridement, one may visualize better the areas that are burned more deeply. The exact depth cannot be estimated at this time, but the deeper the involvement the more

Chart 1.—Comparative temperature curves according to cause of burn.

charred, dull or bluish looking will be these areas; examination will give the operator an insight as to where most of the sloughing will later take place.

The amount of cleansing or scrubbing of the burned areas which have been denuded depends on the type of local therapy that is to be instituted.

If large areas have to be denuded, a general anesthetic should be employed; if less extensive, a narcotic may be used in slightly larger dosage than that which ordinarily would be employed for the age and size of the child. I have used the latter method in the majority of cases, the child cooperating in most instances, the discomfort being slight and the shock involved being no greater than, if as great as, that produced by general anesthesia, and certainly this method entails less danger of pneumonia. First the child is given a cleansing bath from head to foot; then thorough débridement is completed under the best surgical and aseptic conditions possible, followed with the warm wet dressings. Often too much time is employed in debriding the patient, and I cannot emphasize too strenuously that the whole procedure, as outlined, should be completed as quickly as possible, with the aid of several assistants.

CRUST FORMERS

The procedure that employs crust formers or coagulants, such as tannic acid alone, tannic acid in combination with silver nitrate or ointment bases, or solution of methylrosaniline solution alone or in combination, was used in 50 cases (20 per cent). For this group there was an average hospital stay of twenty-two days (table 1). The curve (chart 2) shows, on the average, that on the fifth day the return to normal temperature was effected, but a conspicuous rise is noticed the following day, the temperature returning to normal range on the tenth day.

Here a word of explanation should be given. I learned many years ago, in the early and experimental use of these coagulants, that not only certain areas but also certain types of burns contraindicated their use. At least I found that a great number of the crust-covered areas became infected in spite of the thorough débridement and strict asepsis. I learned also that the greatest number of infections occurred in the deeper or third degree areas. Most of this could be explained by the fact that third degree involvement could not go on to proper healing or restoration without a sloughing of the burned or devitalized tissue in that area. Completely burned or dead tissue, by virtue of its gangrenous

nature, is a good culture medium for pyogenic organisms. Even a mild split or separation in the crust could pave the way for a similar picture, and when an infection becomes manifest diverse ways and means must be employed to counteract it. If the infection cannot be controlled at its original site, other areas beneath the crust become involved by extension, with the result that the crust must be removed. Most of the infections in this series became manifest about the seventh day, hence the rise in the temperature curve on the sixth. Also, I soon learned the fallacy of applying tannic acid or methylrosaniline to the scalp, face, fingers, toes and genitalia.

I think that there is a strong need and many good indications for the employment of the crust-forming procedure, and, like wet dressings, it should not be condemned when and where properly utilized. For this reason the vast majority of cases in which this procedure was used were those of relatively superficial burns which involved chiefly the trunk and which were caused by hot liquids or vapor in 66 per cent as against fire burns in 34 per cent. When the average hospital stay of twenty-two days in these cases is broken down, it is found that those caused by fire require twenty-six days in comparison with only eighteen days for the scalds. Here again it is found that fire played the greater role.

The question arises as to what procedure to employ when a minimum of 40 to 50 per cent of the body surface is involved. In such cases, of course, the prognosis in almost every instance is a very poor one, but occasionally the child pulls through. On these children who are extremely sick and who will hover between life and death for days, sometimes weeks, I believe that one is justified in using the coagulation or crust-forming method, because the patient should be kept at absolute rest while supportive treatment and careful nursing are pushed to the limit, and this regimen the crust formers certainly permit. I believe that just such a procedure may be instrumental in carrying the patient through the early stormy and extremely dangerous period. If wound infections or other complications arise, they may be met at that time. I believe that many lives have been spared by this arrangement; I have encountered at least a dozen such cases. In 1 case 65 per cent of the integument was involved.

TUBBING

The tubing procedure was used in 140 cases (56 per cent). This constitutes the largest group of the four

methods compared and evaluated. In this group there were 106 (75.7 per cent) scalds and 34 (24.3 per cent) fire burns. The hospital stay for the entire group averaged forty-four days, which when broken down reveals that eighteen days were required for the scalds and seventy days for the fire burns (table 1). At first glance this would appear as a startling figure for the fire burns, but it was in this group that most of the

Chart 2.—Comparative temperature curves for different methods of therapy.

cases involving the leg were included. As mentioned previously, the group in which the leg was involved had a grand average of fifty-eight hospital days, with ninety days required for the fire burns of the leg which called for grafting.

In my experience, it has always taken longer for burns involving the leg to heal, and especially is this true when the popliteal space and areas below the knee are involved. It would appear as though this holds true, generally speaking, for the majority of injuries or surgical interventions other than burns involving these areas. For want of some other explanation I have always considered this to be due to a circulatory discrepancy and not to local therapy.

The temperature curve (chart 2) for the cases in which the tubing procedure was employed shows a sharp rise within twenty-four hours, a slight drop on the second day and then a rise to its peak on the third day, from which time there is a steady decline, requiring ten days, however, to fall and remain within the normal range.

The tubing procedure should be classified as a combined method. It has been described in detail in a previous publication.¹

This method has several advantages. The water bath is well tolerated, the wounds and especially the sloughing areas are kept cleaner, relaxation from muscle tension and spasm is afforded after a few minutes and mild exercises of the involved members may be encouraged and started earlier. Contractures may be prevented in the majority of cases, and by not interfering with the granulation tissue the wounds heal rather rapidly or are prepared earlier for grafting. Here again, in an extreme or extensive case, or one of borderline involvement, after the original cleansing bath and débridement the patient may remain in bed for two or three days before the tubing procedure is instituted, the wet dressing method being enforced in the interim.

The tubing method is indicated when the trunk is involved, and especially the genitalia, or when a combination of the trunk and other areas are involved. It is an ideal method when the hands or feet are involved, and at this point I wish to emphasize the use of the continuous water bath when the hands or feet alone are burned. With specially constructed metal fixtures in the form of boots for the feet and long troughs for the forearms and hands, the involved members are submerged for hours at a time, resort being made to wet dressings between dippings. I have observed 2 cases in which, with the water bath alone, spontaneous amputation of one or more toes occurred after a deep burn of the foot in which gangrene had developed.

The aqueous solution of soft soap, if properly made, is nonirritating, and at no time have I encountered a dermatitis or irritation directly attributed to the soap.

COMPRESSION

The compression or closed method offers another approach in the local management of burns. This work is best done in the operating room, where the débridement and thorough scrubbing of the wounds are carried out under general anesthesia, as a rule, and aseptic

technic can be best enforced. The complete multiple dressing, in which sea sponges are embodied, is kept intact for from twelve to fourteen days, after which time the wounds are inspected for healing, infection and sloughing; experience and personal equation being the guiding points for further therapy, grafting or nothing at all, as the case may be. If care is exercised in not getting the compression too great, this method has many advantages. It is based on sound rationale in that it keeps the involved areas at rest without disturbing the wounds, the patient for the most part is comparatively comfortable and the nursing care is reduced to a minimum. However, I feel that this procedure should be limited, in the majority of instances, to selected cases in which certain areas only are involved.

Most of my patients treated by the closed method had burns involving the leg or arm or both, and it is in this type of burn for which I believe this form of therapy is best indicated. For superficial burns of the

TABLE 2.—Complications, with Percentages

extremities, excluding the hands and feet, I think that it offers one of the best solutions to the local therapy approach and it is not only amazing but very gratifying to see the well healed and smooth areas which are effected. However, no matter how carefully carried out, this procedure does not and cannot prevent sloughing in the deeper burns, for reasons previously given. Care must be exercised also in not making the pressure too great over the patella, as a pressure sore and slough may ensue in this poorly padded and superficially protected area.

After the removal of the compression bandage and when sloughing has taken place or still is taking place, it is obvious that further therapy is indicated before restoration can take place spontaneously or before aid can be given by grafting.

It is at this point that, on the removal of the compression bandage and in the face of considerable sloughing, infection or both, one may resort to the tubing method in order to expedite the removal of the slough, to counteracting of the infection and to prepare the part, if necessary, for grafting, solution of sodium hypochlorite or a similar solution being used to replace the wet dressings previously described.

1. Lavender, H. J.: Treatment and Management of Burn Cases, *Am. J. Surg.* 45: 534-538 (Sept.) 1939.

In my series, 20 cases (8 per cent) were treated by the closed method, and I had the good fortune to follow the work done on a similar number of cases in another hospital. The temperature curve (chart 2) shows the rapidity with which the fever was reduced in my group. The length of hospitalization averaged forty-three days—fifty-six for the fire burns and thirty for the scalds (table 1).

Complications in some form arose in 115 (46 per cent) of the cases. Definite secondary pyogenic infection headed the list, with 42 cases (36.5 per cent); acute infection of the upper respiratory tract was next with 34 cases (29.6 per cent); then scarlet fever with 13 (11.3 per cent), pneumonia with 11 (9.6 per cent), otitis media with 6 (5.2 per cent), bronchitis with 5 (4.3 per cent), diphtheria with 3 (2.6 per cent) and whooping cough with 1 (0.9 per cent). Table 2 gives this list. The fire burns showed by far the greater percentage of complications, while, as to method, the crust formers, wet dressings, compression method and tubbing procedure had the greatest percentage of complications in the order named. The percentages were based on the total number of patients treated by each method.

In 46 cases (19 per cent) what would be considered a severe hypertrophic or keloidal condition developed in one or more areas, and these required some special form of therapy for attempted reduction. Thirty of these cases, or more than 65 per cent, occurred in those children burned by fire and where, as a rule, deep sloughs of burned tissue played a role. Only 10 of these patients (4.2 per cent) required some form of orthopedic intervention.

It is well known that some persons are prone to have keloids, and often out of proportion to the amount of damage to the tissue, but certainly this tendency could not account for the large number of keloids presented in this series.

It has been suggested often that if a grafting procedure were to be instituted earlier there would be less chance for keloidal formation. This I would honestly question, for I have seen keloids develop in quite a few cases in which early grafting was done, and even after work done by the most careful and expert operators.

Regarding the time to graft brings up an interesting discussion. I think it is a wise procedure to permit for spontaneous grafting as a rule, because I feel that the results are equal to, if not better than, those in which intervention is instituted. Naturally there is no hard or fast rule as to the time element before grafting. However, in the handling of my patients, as long as there is any evidence of spontaneous healing, with a new island of epithelium appearing here or there, I permit nature to carry on as far as possible. One can usually determine the time to graft by the failure of new epithelial islands to appear, or the lack of extension or coalescence of the islands already evident. Then again a great deal depends not only on the depth of the sloughing areas but on the time necessarily required for the complete separation and removal of these sloughs.

Thirty-six patients (15.2 per cent) required grafting, and all survived. One patient had a homograft with

the father as donor, and the patient held the graft to the astonishing time of over six weeks.

There were 14 deaths, or 5.6 per cent. All the deaths occurred on or before the seventh day, with one exception, which occurred on the ninth day. In other words, every patient survived who lived to the tenth day. Of the 14 patients who died only 1 had an area involvement of less than 20 per cent, and 9 had a minimal involvement of 35 per cent. Only 1 was more than 4 years of age. One death was attributed to shock and occurred the next day after the burn; 8 were due to pneumonia, 3 to a septicemia, 1 to an embolism and 1 to erysipelas.

COMMENT AND CONCLUSIONS

I fully realize that to evaluate something one must compare similar or like conditions. This is obviously difficult to do when one is dealing with burns; however, in presenting the various forms of local therapy in the management of 250 burned infants and children, I wish to make the following general comment:

1. It is of prime importance to resort to systemic or supportive therapy before any form of local approach is considered, and the supportive treatment must be maintained throughout the local management.

2. Burns caused by fire are of greater intensity and usually manifest themselves as third degree involvement. They require greater care and longer hospitalization than scalds, irrespective of the type of local therapy.

3. According to age grouping, infants 1 year and under have the shortest convalescent period, owing to the fact that the majority of injuries are by scalding. Children 2 to 4 years of age present the most serious problems and have the longest hospitalization period. According to location, cases in which there is involvement of the leg require the longest convalescent period.

4. The greater the lapse in time before proper local therapy is instituted the greater the number of infected wounds and the greater the stay in the hospital. "Home remedies" also are a detriment.

5. Débridements should be thorough and complete, aseptic technic being used in all cases.

6. Sloughing of the deep and devitalized burned tissue is part of the natural body defense and cannot be prevented, no matter what type of local therapy is instituted.

7. In spite of condemnation by many workers, wet dressings have their place in therapy for burns; likewise the crust formers, the tubbing method and the compression procedure. Combinations of the methods may and should be used to enhance the desired end result.

8. Secondary infection and irregular sloughing play important roles in causing hypertrophic tissue and keloid formation. Secondary pyogenic infection heads the list of complications, while acute infection of the upper respiratory tract is second.

9. Spontaneous healing should be permitted and encouraged before resort is had to grafting.

10. In a series of 250 burned infants and children, every one survived who lived to the tenth day. There were 14 (5.6 per cent) deaths, with pneumonia topping the list of contributory causes.

One learns by trial and error. Only by facing the facts, being open minded and using logic can one hope to evaluate properly the different forms of therapy. Certain it is that each case presents a problem unto itself, and it is only through experience in the treatment of a great number of burns that personal equation will, as a rule, direct the proper local approach in a given case. I wish to think of it as a selective form of approach and management, taking into consideration the extent, depth and location of the injury, and whether the burn was caused by fire or by scalding.

Then again, perhaps the saying "I treated him, but the Lord saved him," should be given more than secondary consideration.

717 Provident Bank Building.

ABSTRACT OF DISCUSSION

DR. R. H. ALDRICH, Boston: At the Boston City Hospital we average between one hundred and sixty-five and two hundred and twenty-five large burns a year. From 1930 through 1934 our method of choice was the use of a 2 per cent aqueous solution of methylosaniline. In 1934 we modified our treatment, having found that methylosaniline is not a specific antiseptic against the gram-negative organisms. The modification consisted of combining methylosaniline with brilliant green and acriflavine base. This is the so-called triple dye. In his series Dr. Lavender did not lose a burned patient who lived longer than ten days. This is a most important point, as most of the burned patients dying after ten days die of infection. My conception of a burn is that it is a large open surgical lesion usually infected with one of the streptococci. I feel that with the dye treatment, especially with the triple dyes, there is an opportunity to cut infection down to the minimum. Some of the patients of course may be lost as the result of complications such as pneumonia, and patients who have suffered burns involving over 75 per cent of the body area will usually be lost. However, if every burn is considered a potentially infected lesion and treated as such the mortality will be reduced. We do not use the tub treatment. This was stopped many years ago because of the stormy courses that tubbed patients had. The early care of shock is one of the essentials in reducing mortality. I feel that every patient with a burn of 20 per cent of the body area or more should be considered a shock patient and treated as such until it is obvious that he is out of shock or will not go into it. If we are to lower the mortality to the minimum we must stop losing burned patients during the first three days. Once the patient is out of shock, which I attempt to combat by the usual methods of heat, rest and fluids, including saline solution, dextrose, whole blood and plasma, my technic is simple. If the burned area has not been treated with an oil or a salve my débridement consists of taking off only the loose shreds of skin and excising the bleb. I use a 2.5 per cent aqueous solution of the mixture of three dyes, putting on one coat as fast as the previous one has dried. After six or seven coats a flexible eschar is formed, and this, unlike the tannic acid, will not hide infection. It is soluble and will become moist and soft if any pus is under it. If this should happen I elevate the eschar with a pair of tissue forceps, trim it away with a pair of scissors, pat the underlying area with a dry, sterile sponge, and respray. This procedure goes on until new epithelium spreads through the burned area or until the tissues show evidence that they will accept skin grafting.

DR. ADALBERT G. BETTMAN, Portland, Ore.: I agree with most of the statements Dr. Lavender has made; however, I prefer to keep the dressings dry until healing is completed. The treatment of burns resolves itself into the treatment of shock (stopping loss of fluids from edema and weeping and

fixing toxins) and later healing the wound. Heretofore I have tried to heal the wound as the patient was going into shock. Forty per cent of the total fluid shift takes place in the first hour and 60 per cent of the deaths occur in the first twenty-four hours. These are significant statements. Therefore a treatment which requires more than an hour to become effective is to that extent inefficient. Three patients having over 80 per cent (one over 90) of their body surfaces burned have been saved. Albuminuria and urinary suppression do not occur in patients who have not had grease or oil applied. Usually the surface is entirely healed when the coagulum comes away. Tannic acid and silver nitrate solutions seal the surface at once. Of more than 500 burned patients only 16 have been lost; 13 came either in severe shock or died of some condition not related to the burn. The treatment is as follows: A narcotic is given and fluids started, 1,000 cc. for every 25 pounds every twenty-four hours, increased or decreased according to hemoglobin readings. Grease or oil, when present, is removed with ether. Freshly made 5 per cent tannic acid solution is applied followed by 10 per cent silver nitrate. Applications with cotton swabs are best, giving no peripheral ring of moisture the next day. The patient is then placed in a tent heated by electric lights and the surface dried and kept dry (without cold drafts). The coagulum gradually comes away or is removed, at which time most burns are entirely healed. Unhealed areas are epithelized with oxyquinoline sulfate scarlet red gauze. Skin grafting is rarely needed. The average time for recovery is from three to four weeks. Often the skin peels off as a glove, but no fingers or other members have been lost since this treatment has been employed. The solutions are applied to the face as to other parts with the same gratifying results.

DR. H. JERRY LAVENDER, Cincinnati: I agree that the constitutional treatment comes first, and I think it will be recalled that I mentioned that in the premise of my paper. Drs. Aldrich and Bettman haven't agreed with everything I mentioned; therefore I might take two or three exceptions also. I am not against tannic acid or any of the crust formers. I think they have their place, but I think the indications are definitely limited. For scalds they play a marvelous role, but I think they are contraindicated in the types that we know definitely are going to slough. I make that unqualified statement. Otherwise I think there are decided indications for their use. A word regarding homografts: There was 1 case in particular in which a homograft was used from the father. The graft held to the astonishing time of six weeks. As far as I know, that is the longest time on record. We thought perhaps we were going to have, for the first time in medical records, a case in which a homograft was going to hold. We watched it for a long time, and finally at the beginning of six weeks it began to disappear, as all homografts do.

Typhoid Vaccination in the Army.—The use of typhoid vaccine as a protective measure was introduced in the Army, on a voluntary basis, in March 1909, and during that year less than one thousand individuals were protected. This voluntary system was continued through 1910, and by the end of that year approximately 15 per cent of Army personnel had been protected. In March 1911 a division of troops was mobilized in Texas, and for the first time the use of typhoid vaccine was made compulsory for all troops (fifteen thousand) serving in that area. The results obtained in the prevention of typhoid were most excellent. On Sept. 30, 1911 the use of typhoid vaccine as a protective measure for all military personnel was made mandatory, and by the end of that year approximately 85 per cent of all military personnel had been protected. It is evident from the foregoing statements that the full effects of this protective measure did not begin to appear until about 1912. —Immunization to Typhoid Fever: From the Research Laboratories of the Army Medical School, Washington, D. C., Johns Hopkins Press, Baltimore, 1941.

ROENTGEN DIAGNOSIS OF THE PRIMARY TUBERCULOUS INFECTION

C. C. BIRKELO, M.D.

DETROIT

Our present knowledge of the first infection with tuberculosis is the result of a careful correlation of postmortem findings, much animal experimentation and repeated roentgen examinations. Briefly, it may be said that the desire to understand fully this perplexing problem has persuaded all physicians interested in tuberculosis to combine their efforts to the extent that we are now able to say that we have a fairly accurate understanding of the entire primary complex as it occurs in both the child and the adult.

It is a little less than twenty years ago since our knowledge of the tuberculous infection, as it occurred in the child, was so meager and uncertain that the clinician looked on the roentgen examination as only one link in a chain of evidence necessary to decide whether or not the child had tuberculosis. We knew then, as we do now, that the first infection with tuberculosis occurred in the child in the majority of instances. We also knew that the calcium deposits often found in a child's lungs were indications of a tuberculous involvement, and much time and concern were devoted to the finding of such deposits. When they were found, open air schools, summer camps and restricted activities were prescribed for such children. As time went on and we all gained experience, it soon became well known that the first infection with tuberculosis was relatively benign in the majority of instances and that this phase often existed and passed without either the family physician or members of the family becoming aware of its existence.

Since the first infection with tuberculosis was most commonly found in children, it was decided by the National Tuberculosis Association that the first infection should be called the childhood type of tuberculosis and that the later infection, most often found in the adult, should be named the adult type of tuberculosis.

Many objections were made to the term childhood tuberculosis because it was not infrequently found in the adult and especially the young adult. In the 1940 edition of Diagnostic Standards, published by the National Tuberculosis Association, the name childhood type has been changed to the primary phase of tuberculosis, and similarly the adult type is now called the reinfection phase of tuberculosis. In this discussion the names used in the last edition of Diagnostic Standards will be used.

In the primary tuberculous process the method of infection is commonly through the inhalation of the tubercle bacilli into the lung. Occasionally it develops in the gastrointestinal tract through ingestion of infected material. More rarely this infection takes place through the cutaneous route by introducing infected material into a wound or an abrasion.

The first site of this infection in the lungs is the alveolar spaces, which soon become filled with phagocytes, and small areas of consolidation are formed. How many tubercle bacilli are necessary to produce this infection we do not know, but it is known that when they do gain entrance in sufficient numbers to cause infec-

tion they multiply very rapidly and the infection soon extends along the lymphatic channels into the regional lymph nodes. During this period the bacilli grow freely and without much interference. Soon a sensitivity toward the tubercle bacillus develops in the body and an attempt to focalize and limit the infection does occur. Dr. Woodruff has shown by animal experiments that this focalizing begins in from seven to ten days after the introduction of the bacilli. It is because of this sensitivity that we are able to obtain the tuberculin reaction. The permanence of a positive tuberculin test is a disputed question, but it is believed that when the test is permanently positive nearly continuous stimulation has existed. It is however known that, if the primary lesion heals completely, the tuberculin test may again become negative.

During the early stages of the infection there are no symptoms from the primary phase, but with the development of sensitivity a mild fever may occur which passes unnoticed except in a few instances when the infection has invaded a large area of the lung before it has become limited. The parenchymal lesion, when small, will soon become invisible in the roentgenogram, but when it is

Fig. 1.—A, typical primary infection with parenchymal infiltration and lymph node enlargement. B, appearance eight months later; calcium deposits shown in both the parenchymal lesion and the lymph node.

large many months may be required before it clears. Whether large or small, these lesions often cascade and, when caseation occurs, calcium deposits are common. This deposition of calcium was first described by Gohn and has since been called the Ghon focus. This focus may be large or small, depending on the extent of the caseating process.

It has previously been stated that from the parenchymal primary lesion there is a rapid spread or drainage along the lymph channels into the regional lymph nodes. This pathway along the lymphatic channels also suffers some damage from the infection and, when healing has taken place, we find narrow strands of fibrosis along the course of these lymphatics, which often remain for a long time and are frequently visualized in a roentgenogram.

The primary infection is more often discovered only because of lymph node enlargement. In the majority of instances these nodes are large, and more than one group of nodes may be involved by extension through communicating lymphatic channels. Occasionally bilateral node enlargement may be found because of such extension.

When the primary infection recedes, these lymph nodes gradually become smaller, but calcium deposition

is very common in such nodes and extensive deposits may be found, again depending on the extent of caseation.

The lymph nodes not infrequently become so much enlarged that they may occlude a large main stem bronchus and cause an atelectasis. They may also ulcerate or rupture into a bronchus and cause a canalicular dissemination into the lungs on either side. When this occurs, the behavior of the resulting lesions will be the same as in reinfection tuberculosis. The primary nodes may also rupture into the circulation. If it happens to be into a pulmonary artery, the lesser circulation may filter out most of this infection and confine the spread to the lungs; but, if the rupture occurs into some pulmonary vein, hematogenous infection may occur in many organs of the body and meningeal involvement is nearly always fatal. Bone and joint tuberculosis as well as genitourinary involvement is often the result of such accidents.

Such complications should be regarded as accidental happenings, and they are sometimes spoken of as secondary stages of the tuberculous infection. In the majority of cases they do not occur, but one often finds a small parenchymal calcium deposit in the lung and a larger calcium deposit in the neighboring lymph nodes and they are spoken of as results of the primary complex. These evidences of the primary complex may remain for many years and often through the entire life span of the patient.

The primary infection also occasionally occurs in the adult, and I have seen many such cases; their behavior has been the same as in the child. There are some who describe both an anatomic and a clinical difference in the behavior of this lesion in the adult as compared with the child. This is contrary to my experience; but, if it should occasionally appear that a more severe infection has resulted, it is likely that one of the conditions previously mentioned as not uncommon accidental happenings has occurred, as it is known that they occur also in the child.

Sometimes an apparent repetition of the primary tuberculous infection occurs in the same individual. My associates and I have found only 4 such cases, so the condition is very rare. Their behavior was the same in the recurring episode as in their first infection.

This preliminary explanation of anatomic characteristics of the primary infection has been given so as better to understand and appreciate the roentgen findings in a primary tuberculous involvement. In the living person the roentgen examination is often the only method by which one can definitely state that a patient either has or has had such an infection.

The common practice of making roentgenograms of all tuberculosis contacts has made it possible to find the very early primary parenchymal infiltration and to observe its behavior. It has also been possible by serial roentgenograms to correlate symptoms and clinical findings throughout the entire cycle of the primary complex in many instances. Sometimes we have been able to observe the time period from definite exposure to tuberculosis to the first appearance of the primary complex as seen in the roentgenogram. This period is sometimes spoken of as the incubation period and varies from three to eight weeks.

The first roentgen findings of the very early primary lesion, found in the majority of cases, consists of a small area of consolidation in the parenchyma of either lung. The most common location of this lesion appears to be at the middle or basal portions of either lung, but they may also be found at the apexes. In the reinfection type of tuberculosis the upper half of either lung is by far the most common site, and purely basal lesions in this type of the disease occur in about 2 per cent of cases.

There are however, many other disease conditions which produce small and large parenchymal consolidated areas at either the middle or the basal portions of one or both lungs, so the parenchymal lesion is not by itself diagnostic; but when small or large parenchymal infiltrations are found with the regional lymph nodes definitely enlarged, one has the so-called primary complex and a diagnosis can usually be made. More often the parenchymal infiltration has disappeared at the time of the roentgen examination and only a lymph node enlargement is found.

One or more groups of enlarged nodes may be found but they are commonly unilateral. As previously mentioned, an extension may occur to the nodes on the contralateral side, and when this happens Hodgkin's disease has to be thought of and ruled out.

Fig. 2.—A, massive parenchymal infiltration in primary lesion, March 26, 1936; B, bronchial obstruction and atelectasis, April 21, 1937; C, the end result Nov. 30, 1938.

The roentgen appearance of the tuberculous lymph nodes is rather characteristic in this respect: they are often extensively enlarged and out of proportion to clinical findings and symptoms. This finding is so common that it is a mistake to mention adenopathy unless the nodes are clearly seen in a well made roentgenogram. Careless description of uncertain findings will always invite differences of opinion by different observers and confuse the clinician whom we are anxious to help with expert opinion. It is true that there are small nodes and borderline cases in which there is some doubt about visible nodes. In such instances it is our duty to examine further and, if necessary, allow a few weeks to pass and again examine the chest with such roentgenograms as are necessary—such as oblique and lateral projections.

DIFFERENTIAL DIAGNOSIS

In the majority of instances the diagnosis of a primary tuberculous infection can be made from a good roentgenogram. There are, however, a few pulmonary diseases which may produce similar roentgen findings; namely, a parenchymal infiltration with regional lymph node enlargement. This often happens in bronchopneumonia in children, complicating some contagious disease, such as whooping cough. From the roentgenogram alone it may not be possible to rule out pneumonia entirely, but there is usually this difference, that

the lymph nodes occasionally visualized with a pneumonic process are much smaller than those found in the primary infection of tuberculosis. If there is an opportunity to reexamine in a week or ten days, one will find that the pneumonic process has either cleared or formed an abscess. The lymph node enlargement which occurred with a pneumonic process will usually disappear from the roentgenogram at the same time at which the resolution of the pneumonic process occurs.

Clinical and laboratory findings should also be obtained and are always very helpful. The sudden onset of pneumonia and the high fever with a high leukocyte count are often sufficient to differentiate the two conditions. Elevation of temperature in a primary tuberculous process will usually mean complications, such as miliary infiltration or atelectasis from bronchial obstruction, but will not often be associated with leukocytosis.

Hodgkin's disease is often more difficult to differentiate from the primary lesion when the only roentgen evidence consists of lymph node enlargement. In Hodgkin's disease the lymph node enlargement is commonly bilateral and of nearly equal extent on the two

Fig. 3—A, primary lesion with bronchial obstruction and atelectasis, Jan. 12, 1938, B, scar from parenchymal focus visible, Nov. 5, 1940.

sides. They are also often extensive and progress rather than retrogress, so that in the roentgenogram of Hodgkin's disease the mediastinal border has a scalloped appearance. In the primary tuberculous lesions the nodes are more often unilateral and they commonly retrogress and become smaller after the parenchymal lesion has disappeared. If differentiations cannot be made from the roentgenogram, the patient with Hodgkin's disease will soon acquire generalized adenopathy, and biopsy will then be possible.

Few laboratory tests are of much value in differentiating the two conditions, but a tuberculin test should be made, and if it is negative it will be helpful. A differential blood count may occasionally help, but in itself it is not diagnostic. Reexamination with the roentgen ray is more informative, because in Hodgkin's disease there is often rapid extension and the tuberculous nodes commonly become smaller or retrogress.

LUNG ABSCESS

Lung abscesses are quite common in children and the young age groups and on a roentgenogram may resemble many other diseases, among them primary tuberculosis. In the child they are often the result of inhalation of foreign bodies. The opaque foreign body can often be found and should always be borne in mind and looked for. The nonopaque foreign body such as the peanut

is very common, and one variety will invariably produce an abscess. It nearly always produces bronchial obstruction and atelectasis and, when this finding is not very definite, inspiration and expiration films should be obtained and the change in air content of each lung and the shifting of the mediastinum will be noticed when bronchial obstruction is present. Lymph node enlargement is generally lacking in an abscess and very prominent in the tuberculous primary lesion. If there is an opportunity to observe the lesion and to obtain serial roentgenograms, the lung abscess will excavate in a very short time. The parenchymal lesion in primary tuberculosis nearly always becomes smaller, and excavation does not usually occur. Laboratory methods should be made use of; leukocytosis will frequently be found in an abscess and a normal count will be found in most cases of the primary tuberculous infection.

CYSTIC DISEASE

Cystic degeneration occurs in the child as well as in the adult, but it ordinarily resembles fibrosis from a healed tuberculous process rather than an active primary infection. There are, however, symptoms such as hemoptysis with cough and expectoration which often brings them in for a roentgen examination. The outstanding roentgen finding is localized or generalized fibrosis with areas of rarefaction, sometimes resembling excavations. The location of the lesion in the lungs, like a lung abscess, may be anywhere, but there is rarely any lymph node enlargement, whereas in the primary infection the lymph nodes are unmistakably enlarged. In recent years we have found so many of these patients with cystic disease that we have learned to identify them from the roentgenogram, and the diagnosis can generally be arrived at by instilling iodized oil, which easily enters the cystic areas and then establishes the diagnosis.

BRONCHIECTASIS

The most common cause of hemoptysis in the child and young adult is bronchiectasis, and for this reason we have many of these cases reported to us for roentgen examination. They almost always give a history of repeated attacks of pneumonia and influenza, and whenever the common cold invades their family circle they are the ones who suffer the most. The colds will last for weeks in a bronchiectatic child, whereas a few days is the common course of this disease in the otherwise normal person. In bronchiectasis the x-ray findings are nearly always at the base of either lung. The bronchiectatic areas become infected often and the roentgen findings are then a mottled appearance at the base. These ordinarily do not produce any large areas of consolidation like the pneumonic infiltration but rather a scattered mottling with very small areas of consolidation. As the infection clears, these small areas of consolidation will also clear only to reappear with the next upper respiratory infection. Bronchiectasis is usually not associated with any lymph node enlargement. An instillation of iodized oil will nearly always establish the diagnosis, and the cylindric or saccular variety of bronchiectasis will be found, depending on the extent of the disease.

ATELECTASIS

Atelectasis indicates some bronchial obstruction and may occur as a result of foreign bodies or tumors within the bronchus or from contraction of scar tissue as the

result of ulceration within the bronchus. It may also be produced by pressure on the bronchus from without.

It is not uncommon to find that the lymph nodes in a primary tuberculous infection compress a main stem bronchus to the point of occlusion and cause a considerable area of atelectasis. The roentgen examination may not disclose the cause of such bronchial obstruction but it should record or suggest the possibility of atelectasis and describe lymph node enlargement when present and demonstrable. It will lead the way to further investigation, such as bronchoscopic examination which will often give positive information and may lead to removal of the obstruction and reestablishment of aeration through the atelectatic area.

Taylor and Hamilton avenues

ABSTRACT OF DISCUSSION

DR. FREDERICK SLYFIELD, Seattle. In the event that we look on what we have been accustomed to calling primary tuberculosis or the primary complex or childhood tuberculosis as clinical disease, are we to assume that every time we get a positive tuberculin test we must call that tuberculosis? In that event it seems to me that we are going to be in for a great deal of difficulty. I should like to have that point clarified.

DR. RALPH S. BROMER, Bryn Mawr, Pa. As a roentgenologist I regard the use of the oblique films as most important. They are of aid in demonstrating enlarged lymphatic nodes lying at the bifurcation of the trachea, the other nodes of the tracheobronchial group and also the paratracheal groups. I have found the latter frequently involved in postmortem examinations. In many cases of tuberculous meningitis enlarged nodes have not been demonstrated in films of the chest in the search for the primary focus because of failure to secure oblique films. In survey work in children, the single anteroposterior view frequently fails to demonstrate enlarged nodes, evidence of primary infection. It is sometimes possible to demonstrate in roentgenograms enlarged nodes and parenchymal involvement as part of the primary complex in patients who have a history of positive contact and also have a positive tuberculin reaction. But usually it is impossible to say in cases of moderate or extensive parenchymal involvement whether or not one is dealing with a primary infection or a reinfection.

DR. C. C. BIRKEL, Detroit. I am sorry that I did not take the time to read the entire paper, because in it I tried to explain the thing the clinician wants us to do. He wants us to describe what we see in the films that we make, and it does not make any difference how many films one wants to take in order to make the diagnosis. We do know that the first infection is nearly always in the lymph nodes. We know that these patients behave in a certain manner. They do not need any collapse therapy. If you take them away from the source of infection so that they don't live in an atmosphere of open contact with tuberculosis they do well without any other treatment. On the other hand, when one begins to see cavities one has to do something. It is then a question of therapy, and the clinician depends on an x-ray man to decide whether it is primary or reinfection. They ask me those questions every day, and I try to answer them. Sometimes I can, sometimes I cannot. The National Tuberculosis Association has definite views as to terminology.

DR. HORTON R. CASPARIS, Nashville, Tenn. I am not criticizing Dr. Birkel for following that terminology. I am bringing up the question because I think eventually we all have to get away from that situation. I don't think it is quite fair to ask you to make that distinction. Clinicians too often ask the x-ray man to do everything for them. We have got to do this together. A good x-ray man is going to show us oblique films. Everything has got to be on an individual basis. We have got to have a series, we have got to have oblique films we have got to have everything that radiologists can decide in any individual case. Regarding the question of calling everything tuberculosis I think that if one were able to

do autopsies on all those with positive tuberculin tests one would find active tuberculosis but not enough. Similarly, if one takes out any tonsils one always finds a pathologic condition in the tonsils but one doesn't call it tonsillitis. I would suggest that we make the differentiation and say we have tuberculous infection, and then with all the means at our disposal, if we think that infection is causing the patient enough trouble to necessitate our doing something about it, modifying in any way his behavior or his existence, we are treating and then we can call that tuberculosis. That would be a practical differentiation—infection, then tuberculosis. It is true that more tuberculous infection is seen in children, a greater incidence of certain types of tuberculous infection, probably, than in adults. But one often sees the same type in children that one sees in adults, and in adults certainly young adults, one sees the same type one sees in children. Tuberculous infection may come in these seizures and, as we go along, suddenly these persons become ill and we find some reason for it, then it is tuberculosis.

NECK PAIN

THE LAMINAGRAPH AS AN AID TO THE DIAGNOSIS OF ATLANTO-OCCIPITAL LESIONS

FREDERICK A. JOSTES, M.D.

Assistant Professor of Clinical Orthopedic Surgery, Washington
University School of Medicine, Commander, U. S. M. R.
ST. LOUIS

Pain in the neck or occipital region with radiation toward one or both shoulders usually follows a recognizable symptom-sign syndrome which can be accurately diagnosed and effectively treated. There are other cases in which, while the clinical picture and physical manifestations are certainly clear cut, the examination and roentgenograms have heretofore failed to reveal any demonstrable pathologic condition.

In the past we have encountered such patients who were suffering from a type of neck pain which had been resistant to all attempts at satisfactory analysis, to say nothing of their complete impassiveness to the usual forms of therapy. Repeated and persistent efforts to identify the condition as bursitis, tendosynovitis, periarthritis, cervical rib phenomenon, anterior scalenus syndrome, supraspinatus disturbance, a localized myofascial lesion or, in some cases, even anatomic changes in the cervical vertebrae failed by all diagnostic as well as therapeutic tests. The ordinary roentgenograms of the cervical and shoulder regions in these cases repeatedly had been pronounced negative. The patient usually had seen every one, had tried everything and felt no better.

Finally, the physician came to segregate this group by the simple expedient of observing their response to intermittent sessions of head traction. This type of therapy generally brought a satisfactory response by relieving the patient of pain and again allowing him the normal ranges of motion. While the patient was grateful the physician was still not completely happy because of his inability definitely to classify the pathologic condition and because this particular therapeutic effort remained in the category of the empirical.

With the advent of the laminagraph, a new field of pathologic possibilities was opened up. This type of

From the Department of Surgery, Washington University School of Medicine, and the Mallinckrodt Institute of Radiology.

Read before the Section on Orthopedic Surgery at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

roentgenography, so-called body section roentgenography, can discard, in a manner of speaking, the overlying maxilla and present only the plane of the occipital condyles and the atlanto-occipital joints in sharp focus, exceeding therefore the limitations of the field visualized in the routine anteroposterior view through the mouth. Body section roentgenography as defined by Dr. Sherwood Moore,¹ who in collaboration with Mr. Keiffer of Norwich, Conn., perfected the instrument called the laminagraph, is a type of roentgen examination whereby a particular section, plane or layer of the body can be visualized with more or less complete exclusion of other layers. Continuing the delineation, he explains the physical principle as one in which during exposure a synchronized coordinated movement of an x-ray tube and film takes place about a fixed axis in such a way that shadows of objects in this axis maintain a constant relationship to the film and tube, while objects not in this axis have a shifting relationship so that their shadows are dispersed. Simply by way of further elucidation it may be stated that body section roentgen-

occipital condyles are symmetrical and sit evenly and squarely on the superior articulating facets of the atlas. The atlanto-occipital joints, heretofore obliterated by the superimposed dense shadow of the maxilla, are presented in clear detail and are seen to be smooth and equidistant. The lateral masses of the atlas are similar in both vertical and horizontal dimensions. The odontoid process of the epistropheus, or second cervical vertebra, is intact and free from irregularity. The articulating surfaces between the atlas and second cervical vertebra are smooth, equidistant and sit squarely one on the other.

PATHOLOGY

The laminagram has disclosed various types of abnormality to the orthopedist so far as the occipital condyles and atlanto-occipital joints are concerned. The occipital condyles themselves may be asymmetrical or they may be displaced on the atlas so that there exists an atlanto-occipital subluxation. This may be the result of an acute traumatic incident. The atlanto-occipital joints may present various lesions: There may be a congenital

Fig 1—A, negative laminagram of atlanto-occipital joints at 8 cm depth showing relation of occipital condyles to first cervical vertebra and of first cervical to second cervical vertebra. B, anatomic specimen, decalcified, and sectioned in frontal plane through midpoint of odontoid process, demonstrating anatomic field outlined in A.

ography has found its greatest field of usefulness in the study of various pathologic conditions in the respiratory tract from the sinuses down to the various pulmonary conditions and, second, in parts of the axial skeleton. With special reference to the latter, it has been demonstrated that the first three cervical vertebrae can be studied and understood roentgenographically only by means of this body section method. Selecting patients with neck pain who did not respond to the usual types of therapy but did obtain relief from intermittent sessions of head traction, we therefore began submitting them to routine laminagraphic examination of the occipital condyles and contiguous joints.

NORMAL ANATOMY

In a laminagram disclosing a normal occipitocervical region (fig. 1), the base of the skull, the occipital condyles, the atlanto-occipital joints, the first and second cervical vertebrae with intervening joints and the odontoid process are well visualized and clearly defined. The

fusion of one articulation or both; there may be arthritic changes involving one or both sides—possibly more advanced on one side to the point of partial or complete obliteration of the joint; as previously mentioned, there may be a subluxation of the joint. The lateral masses may be asymmetrical, as in a fracture of the atlas. In such instances, one lateral mass as the result of compression may be asymmetrical in the vertical and horizontal dimensions as compared to its opposite fellow. The odontoid process may be irregular, may be fractured through its base, may be tilted or may be actually dislocated. The articulating facets of the first and second cervical vertebrae may show arthritic changes, may be asymmetrical or may be dislocated one on the other.

CLINICAL SURVEY

The clinical pictures of some of these lesions, apart from the frankly acute traumatic, have been neither simple nor clear cut. For instance:

CASE 1—R C, a woman aged about 63, was seen for the complaint of pain about her neck on the right side behind the ear and about the right shoulder. The pain was more severe in the shoulder region and there was localized tenderness about the

1. Moore, Sherwood. Body Section Radiography, *Radiology* 23: 605 614 (Nov.) 1939; Body Section Radiography with the Laminagraph in Pulmonary Disease, *Am. Rev. Tuberc.* 38: 538 556 (Nov.) 1938; Practical Applications of Body Section Roentgenography, *Am J Roentgenol* 44: 24 30 (July) 1940.

bicipital groove as well as some tenderness referable to the insertion of the deltoid. There was limitation of all movements of this joint. She also complained of dizziness and uncertainty in walking at times. Before she was seen by us another physician secured a roentgenogram of the involved shoulder which revealed calcification in the right subdeltoid bursa. She was treated for subdeltoid bursitis by means of infra-red heat, exercises and diathermy and received a high voltage roentgen treatment. Following this, the pain became more acute. When the patient was examined and the roentgenogram seen, the therapy of multiple injection and aspiration of the bursa immediately came to mind. However, limitation of motion was demonstrated in the neck as well as some tenderness over the right atlanto-occipital joint and over the spinous processes of the lower cervical vertebrae. Before the aspiration was carried out, routine roentgenograms of the cervical vertebrae and the opposite (left) shoulder joint were taken, as well as laminagrams of the atlanto-occipital joints. They disclosed the

to the right. There was radiating pain to the left side of the neck, skull and face; there were also attacks of dizziness. All movements of the neck were definitely limited. She had occipital headaches one to three times a month. She had seen many specialists. She had not succeeded even temporarily in obtaining relief. Her head was held with a list to the left. Because the ordinary roentgenograms of the cervical spine had always been pronounced negative and she had been told repeatedly that there was nothing wrong with her neck in spite of the limitation of motion, she began to be a psychic problem as well. Laminagrams (fig. 2) disclosed a compression fracture of the lateral mass of the atlas on the right side. Also a suggestive posterior subluxation of the occipital condyles on the first cervical vertebra plus an angulation deformity of the shaft of the odontoid were demonstrated at about the midpoint by good detail lateral views. There was immediate relief from pain during sessions of head traction and her neck movements returned to their approximately normal range of motion. Tem-

Fig 2—Lateral views of cervical vertebrae. A, showing apparent posterior displacement of occipital condyles on atlas. B, postural correction; also deformity of odontoid process. Questionable old fracture. C, routine anteroposterior view of first and second cervical vertebrae through mouth, showing diminution of joint space at arrow on right. D, anteroposterior laminagram of same area showing diminution in vertical dimension of lateral mass on left (old compression fracture) and narrowing of joint space on right between cervical vertebrae 1 and 2.

following: beginning calcification in the left subdeltoid bursa, hypertrophic osteoarthritis of the cervical spine and, in the instance of the laminagram, arthritis of the right atlanto-occipital joint. Since the shoulder abnormalities were now bilateral, although the left was asymptomatic, and in view of the cervical disturbance, the injection and aspiration were deferred until a trial at intermittent head traction was employed. On the first trial of head traction and while being thus suspended, she was happy to find that she was free from pain and could move the involved shoulder joint almost throughout the normal range in all directions. Following the use of intermittent head traction and the subsequent wearing of a Thomas collar, she became asymptomatic.

CASE 2—J. H., a woman aged 23, complained of pain in the neck of ten years' duration. The onset was associated with an accident on a sled. The symptoms were aggravated four years later when further trauma to the head and neck occurred during a motor car accident. The pain in the neck was continuous; it was increased when she rotated her head

porary use of a Thomas collar was followed by complete relief from pain.

CASE 3.—T. C., a woman aged 58, had been employed many years in a knitting mill handling a box-stapling machine. She maintained an average of one hundred staples a minute, so that her head was incessantly in motion turning to the right and back again. She also recalled having injured her head and neck in an automobile accident many years before. She complained of pain in her neck and at the base of the skull for the past two years, as well as a "grinding" sensation on turning her head. She felt that the pain was worse when the weather was bad. There were intervals of dizziness and attacks of headaches. She had limitation of motion to the right. Laminagrams of the occipital condyles (fig. 3) revealed a narrowing of the joint space between the occiput and the first cervical vertebra on the right as compared to the left. There was also a diminution in the vertical dimension of the lateral mass of the first cervical vertebra on the right as compared to the left. The joint space between the first and second cervical

vertebrae on the right was narrowed. The diagnosis was therefore traumatic arthritis of the cervical spine and, because of the diminution in the lateral mass on the right side, questionable old compression fracture of the first vertical vertebra. Intermittent sessions of head traction and the wearing of a Thomas collar caused a great deal of improvement.

CASE 4.—M. F., a woman aged 47, sustained an injury, revealed in a laminagram, during a motor car accident and

Fig. 3.—Anteroposterior laminagram of occipital condyles demonstrating narrowing of joint space between occiput and first cervical vertebra on right and between first cervical and second cervical on right (old fracture of lateral mass).

subject to attack only in weight bearing attitudes. There was a feeling of fullness on the right side of the neck and a grating sensation at the base of the skull on movement. This was further complicated by an increasing difficulty in swallowing. He was placed in bed in sustained head traction for several days. After the first few hours, the pain in the neck disappeared and he was able to swallow normally again. He was soon allowed up, receiving intermittent sessions of head traction, wearing in the intervals a supportive Thomas collar. On his discharge he was given a head traction unit to use in his home at intervals during the day. He obtained immediate relief from his neck symptoms, but whether this status can be maintained in the face of the alcoholism is questionable. However, he has been asymptomatic for a year.

Laminagrams (fig. 4) disclosed a congenital anomaly associated with the transverse process of the first cervical vertebra with a pseudarthrosis between it and the base of the skull.

Fig. 4.—A, regular anteroposterior view of first and second cervical vertebrae through mouth, not demonstrating any remarkable pathologic condition. B, anteroposterior laminagram of same area demonstrating congenital anomaly of transverse process of first cervical vertebra with pseudarthrosis between its outer end and base of skull. C, lateral view of same area demonstrating spinelike process on superior rim of atlas.

The lateral view disclosed a hypertrophic spur on the anterior portion of the atlas.

CASE 6.—C. P., a man aged 62, contracted a painful neck and right shoulder, with pain radiating down the right arm to the fingers, while exposed to inclement weather during a hunting trip. The first physician on his return to town gave him diathermy treatments and injections of vitamin B₁. He had his teeth checked by a dentist. He went to another physician, who took roentgenograms of the shoulder, saw no anatomic

changes and told him that the pain would probably disappear. He then spent six weeks in the South. Without having obtained relief, he saw another dentist, who extracted three of his teeth. Besides pain persisting in a radiating manner down the right arm, he began feeling some pain down the left arm. There followed ten days at a health resort at which he took the baths. He returned to town with the same complaint, saw another physician and started diathermy treatments again. This proved futile. He next tried a physical therapist, who administered diathermy, electrical stimulation to the neck and arms, massage and Scotch douches. He also had resumed taking vitamin B pills. With no relief, he sought the advice of a neurosurgeon. Although the latter declined to accept the case, he did suggest an electric vibrator. He next saw two orthopedists, the one telling him that there was nothing to be done but to "grin and bear it," the other taking more roentgenograms of the shoulder in which a calcified mass in the subdeltoid bursa could not be demonstrated. Multiple injections and irrigations with procaine hydrochloride and saline solution were carried out. This proved valueless, so he went to an internist and was placed on a course of sulfanilamide. Following this he received a course of injections with bee venom. As a final effort he had his sinuses checked by an otolaryngologist, but this examination revealed nothing of moment.

In spite of the varied therapies which he received, he presented himself in July 1940 with pain in the neck radiating down to the shoulder on the right side, about the right shoulder blade and down the right arm. There was a sensitive area to pressure in the region of the head of the radius. His right hand, both on the dorsum and in the palm, seemed numb at times. He had intermittent pain radiating down the left upper extremity.

At this time laminagrams of the cervical vertebrae revealed a definite right atlanto-occipital arthritis. There were osteoarthritic changes between the fifth, sixth and seventh cervical vertebrae. After three weeks of intermittent sessions of head traction and the wearing of a Thomas collar, the peculiar pain in his forearm and hand disappeared and the neck pain subsided. At the present time he is completely recovered.

CASE 7.—E. M., a woman aged about 52, had been subject to rather severe occipital headaches, pain in the neck and pain radiating down the left shoulder and arm for a year. She had had vague intermittent pain in the neck for many years. She was told that "it was nerves and that she would be forced to take it." Movement of her head to the left was limited as well as limitation of abduction and internal and external rotation of the left shoulder. The ordinary roentgenogram in lateral view showed arthritic changes of the cervical vertebrae

The laminagram disclosed an atlanto-occipital arthritis on the right side. The film of the left shoulder showed no changes. Following head traction the headaches disappeared, pain in the neck and shoulders subsided and the movements of the neck approximated normal. With regular exercises, the movements of the shoulder joint became of full range.

CASE 8.—J. K., a university student, while tumbling sustained an injury to his neck. The neck became stiff, the head was tilted to the right and there was decided limitation of motion.

to the left. Laminagrams (fig. 5) taken shortly after the accident disclosed a rotary subluxation of the occiput on the atlas to the right, as well as a mild rotary subluxation of the first cervical on the second to the left. Reduction by traction and mild manipulation cleared away the symptom complex.

CASE 9.—E. R., a woman aged 35, complained of a painful neck of some eleven years' duration. She had never been able to acquire any appreciable relief even for temporary intervals. More recently she was having pain about the roof of her mouth

arms across his chest, bringing the shoulders forward, most of the traction force can be diverted toward the posterior part of the neck and shoulder muscles. By moving his hips forward and hiking his pelvis he can transmit this force to the paravertebral low back muscles. Such a traction session is carried on for a period of from one to several minutes; traction is then released and the patient is allowed an interval of rest

Fig. 5—A, anteroposterior view of cervical vertebrae showing tilt of head to right but no demonstrable abnormality. B, anteroposterior view through mouth of first and second cervical vertebrae, demonstrating rotary subluxation of cervical vertebra 1 on 2. C, anteroposterior laminagram disclosing rotary subluxation of occiput on atlas to the right as well as mild rotary subluxation of cervical vertebra 1 on cervical vertebra 2 to left.

on the right side, about the right temporomandibular region and radiating down the right side of the neck along the paravertebral muscles. She complained of a grating sensation on rotation of the head and a crawling sensation over the right side of the face. Because of the temporomandibular pain and occasional ringing in her ears, as well as a tendency to grit her teeth for relief, she was seen by an otolaryngologist and dentist, whose examinations were negative. Laminagrams (fig. 6) of the occipital condyles revealed an arthritis of the right atlanto-occipital articulation and an irregularity of the joint. She obtains relief from her attacks by the use of intermittent head traction and a Thomas collar. Her attacks, while they do occur, have done so with less intensity and less frequency.

TREATMENT

The apparatus used for head suspension both as a diagnostic and as a therapeutic aid is composed simply of the ordinary Sayre head traction apparatus. We have made up our own head halter of canvas, which is more comfortable than the usual leather types. Intermittent head traction is obtained by adjusting the traction apparatus with head halter to the patient and having him rise on his toes as high as possible. The traction unit is then made secure at this level and the patient gradually lets his heels down until they approximate the floor. Usually there is sufficient traction by this method to allow for whatever painless manipulation of the neck is desired. The patient is taught to relax completely. Usually the range of active movements in traction is then checked by allowing the patient to move his head to the right, to the left, in hyperextension and in flexion. These movements are then passively carried out to their complete range of motion. By flexing his head and folding his

This procedure is usually repeated three or four times. The amount and duration of the traction force is carefully gaged to the comfort and tolerance of the patient.

Other phases of the treatment are variable and adapted to the individual case. A rather acutely painful neck as well as a chronically painful one may require a preliminary treatment of infra-red heat. The sessions of intermittent traction are spaced according to the need; they may be employed daily, every other day or several times a week. This may or may not need to be

Fig. 6—A, anteroposterior view through mouth, not demonstrating any notable pathologic condition. B, anteroposterior laminagram of occipital condyles showing right atlanto-occipital joint irregularity and arthritis.

supplemented by the wearing of a Thomas collar. In very severe or very resistant cases, prolonged head traction in bed may be necessary for a time. While thiamine hydrochloride and salicylates may be employed in these cases, it is preferable not to employ any agent which will in itself obliterate pain during the early phase of treatment, for these agents may mask the picture and give an illusion that the traction method is both a diag-

nostic and a therapeutic success. These patients, especially chronic sufferers, are often nervous and mentally disturbed because of the acute or prolonged siege. Very small doses of bromides temporarily administered are effective in helping them to regain their poise and self assurance while undergoing treatment.

COMMENT

There are many patients who present themselves with the complaint of neck pain or pain radiating about the shoulder. It has become apparent that a considerable number of these have their source of irritation in the cervical vertebrae rather than in the shoulder region, and in spite of negative routine roentgenograms of the cervical vertebrae laminagrams have demonstrated the pathologic condition to be about the occipital condyles and atlanto-occipital joints.

One immediately begins to concern oneself about the distribution of pain in these instances. The possibilities are: first, pain emanating from muscle imbalance or spasticity secondary to joint derangement (somatic pain); second, pain emanating from irritation of the root of the nerves as they emerge from their bony foramina (radiculitis).

Somatic pain may be a wily symptom. When it arises in skin or in exposed mucous membrane, the site of pain may be accurately indicated. But when pain arises from the deeper somatic structures, such as muscles and joint attachments, the localization may become a problem. A classic example of this is the referral of pain to the knee when the hip joint is involved. Muscle pain is disagreeable, diffuse, continuous and difficult to locate. If the patient, for example, feels the pain at the time he is describing it, he may localize it fairly well. At other times he may impress one as being very vague about this most disturbing annoyance. In cases of "fibrositis" and "myalgia," tender spots may be giving rise to widespread referred pain and even to areas of referred tenderness. A strained joint gives rise to a "dull ache." Strain on the muscle or aponeurosis attached to the occiput may produce occipital headache. So, too, pain arising from root pressure (radiculitis) may present a pattern of long range radiation. Phrenic irritation at the level of the first and second cervical vertebrae may give rise to pain over the lower ribs on one side aggravated by coughing or sneezing, as a result of spasm of the diaphragm. In the same area occipital neuralgia and occipital headache are frequently referred along the posterior divisions of the corresponding cervical nerves. Pain may be referred along any of the branches of the superficial cervical plexus from the third and fourth nerve trunks and may be attended with severe cervical and posterior auricular neuralgia.

While somatic pain may arise independently of root irritation, root irritation would seem to be always accompanied by some type of somatic pain. Hence there is possible the blending of the two pain patterns in many clinical pictures with the resulting confusion as to proper and accurate allocation.

Since some of the occipitocervical lesions presented have bony abnormalities which are not, figuratively speaking, erasable, it stands to reason that the symptom complex in some of these cases may not be permanently allayed. Patients do obtain immediate relief in many instances and prolonged relief in as many more by the head traction therapy as outlined. But such a lesion as a unilateral atlanto-occipital arthritis is always susceptible to an acute exacerbation if the patient disregards the proper measures for protection.

CONCLUSION

Occipitocervical lesions, heretofore obscure because of the limitations of the ordinary roentgenograms, are now demonstrable by body section roentgenography.
3720 Washington Boulevard.

ABSTRACT OF DISCUSSION

DR. W. EDWARD CHAMBERLAIN, Philadelphia: I have been interested in the upper end of the cervical spine. My associates and I encountered a group of cases in which anomalies of this region turned out to be causing pronounced neurologic changes. There are all gradations of anomalies in this upper region. In 1 case there was a failure of segmentation at the fourth and third cervical vertebrae. All are familiar with congenital fusion or developmental anomalies in which segmentation was faulty in all parts of the spine. In another case a failure of segmentation occurred between the second and third cervical vertebrae. In 1 case failure of segmentation involved a large segment of the cervical spine. In a case in which an anomaly was present, this failure of segmentation occurred between the second occipital and the first cervical, with fusion of the atlas and the base of the skull. The boy had syringomyelia, which was cured by surgical operation which included the removal of the dorsal part of the foramen magnum and the dorsal part of the atlas. A girl had all of the symptom complexities of multiple sclerosis. She was cured by removal of the dorsal part of the foramen magnum and the dorsal part of the fused atlas. A boy died from syringomyelia before we discovered that we could have done something about it because the condition was caused by sclerosis of the canal and foramen magnum. In roentgenographing this part of the spine watch for elevation of the first and second cervical vertebrae, which goes with this condition. I wish to emphasize the usefulness of the open mouth technic even though we have the laminagraph, because it helps us to see what the relationship of these parts is to the base of the skull. In the open mouth technic, if the edges of the teeth and the base of the skull are superimposed, the deltoid process will show up in the open mouth and so will most parts of the first cervical or the atlas. In a case of platybasia, a developmental anomaly of the first cervical and second occipital, with the edges of the teeth approximately at the base of the skull the deltoid process was seen way up inside the skull.

DR. SHERWOOD MOORE, St. Louis: The types of patients with the histories presented are great sufferers, and diagnosis and treatment are most difficult. A neglected neck injury may and frequently does produce a neurotic state which is quite characteristic, enough so that a description of an individual case has been written up in humorous vein in one of our monthly magazines. Dr. Chamberlain's statement regarding the film of the first cervical vertebra made through the open mouth is of utmost importance. However, upper cervical traumas and anomalies are the bane of the radiologist when he is limited to conventional methods of x-ray examination. With conventional methods, stereoscopic films, films from different angles, there is a need for something additional. This is fulfilled by the laminagraph. It should be mentioned that other appliances of this type may be helpful, but not one of them is as efficient as the laminagraph. It should be pointed out however that, with all new advances, standard radiologic and physical methods cannot be discarded. The laminagraph is most helpful in the cervical region, as it is in all similar regions where there is a maximum superimposition of structures obtained on the x-ray negative. These shadows can be largely eliminated with the laminagraph.

DR. MARIUS N. SMITH-PETERSEN, Boston: Did the physical findings and distribution of subjective pain correspond in your cases to the x-ray findings or were your diagnoses always based on the x-ray appearance alone?

DR. FREDERICK A. JOSTES, St. Louis: To answer Dr. Smith-Petersen I would say that the physical findings were definitely referable to the lesion, that they were at times confused, as was mentioned in the paper, with cervical radiculitis from arthritis.

of the fourth, fifth, sixth and seventh. With reference to the open mouth roentgenogram, sporadically we have had excellent results with the simple roentgenogram also, but one probably roentgenographs 50 or 60 patients before one sees a good one. Incidentally, many of these patients, as Dr. Sherwood Moore has mentioned, become neurologic and psychiatric problems. They go from pillar to post without relief, and pain is intense. If I did not mention it—and Dr. Lewin called my attention to it—great occipital radiation is a very important symptom. These patients also have pain in the ear and, as this one woman described it, she had a peculiar crawling sensation over that side of her face. The mouth does not escape involvement, particularly the hard palate.

CARCINOMA OF THE LUNG OF LONG DURATION

ALFRED GOLDMAN, M.D.
SAN FRANCISCO

Hardly a series of cases of carcinoma of the lung has been reported without mention of some cases in which the duration was two years or more. In Brunn's¹ series (1926) there were 20, or 7.5 per cent, of cases in which the disease had such a duration. In the reports published before 1932² it is unlikely that adenoma was differentiated from carcinoma. It seemed advisable

to review our cancer material to determine whether, exclusive of possible adenoma, cancer of long duration existed. Eleven cases of cancer of a duration of more than two years, proved histologically, were encountered and studied. In the course of the study certain data were discovered which may be a clue to earlier recognition of some types of carcinoma.

Fig. 1 (case 11).—Roentgen appearance on Oct. 15, 1937. Overlying the third rib anteriorly is an irregular density.

The age distribution of the patients was not remarkable, the ages ranging from 40 to 70. But wider variations are found in larger series. All the patients were men, but only 91 per cent of my last 111 patients with pulmonary cancer were male. The high incidence of cancer in men over 40 offers aid in differentiating the slowly growing tumors from adenoma, since nearly two thirds of patients with adenoma have symptoms before 40 and the same proportion are female (12 of my 19 patients). Furthermore, in our experience when the diagnosis of polypoid bronchial tumor could not be decided during life and the patient was a man over 40 the diagnosis at necropsy was a malignant tumor.

The pathologic changes did not vary much from those reported by others for tumors of the same histologic types. It was noted by Brunn¹ and Gebauer³ that epidermoid carcinoma tended to remain more localized than other types, although exceptions existed. It is noteworthy that 10 of my 11 patients had epidermoid carcinoma, while only 1 had alveogenic carcinoma. Although in all our patients with adenocarcinoma the disease had a relatively short duration. Gebauer has reported on 1 whose tumor had a clinical course of four years. He noted, as my associates and I have, the difficulty in distinguishing adenoma from adenocarcinoma.⁴

The location of the 11 tumors is of interest and in general would support the observation of Neuhof⁵ that peripheral circumscribed carcinoma is of longer duration than carcinoma in a large bronchus. Since at postmortem examination it is often difficult to determine the site of origin of carcinoma, this is best determined from roentgen and bronchoscopic studies during life. In only 2 of our patients could the tumor be classed as central; in the remaining 9 it was peripheral.

Fig. 2 (case 11).—Appearance Jan. 31, 1940. The tumor mass occupies the entire atelectatic upper lobe of the right lung.

Fig. 3 (case 4).—Postmortem specimen. Note the ten enlarged mediastinal lymph nodes. There was no carcinoma in any of them. Note the invaded diaphragm and ribs.

During the growth of the tumor, which may fill an entire lobe, the earliest roentgen studies may reveal a small peripheral mass which as it grows into a large bronchus produces a large opacity in the films and bronchoscopically becomes visible as a tumor, so that

one would say that it was of central origin and location if one did not have knowledge of the earlier site (case 11, figs. 1 and 2). The tumor in the stem bronchus was localized, produced an annular constriction (case 6, fig. 4) but was not polypoid. The lobar site of the primary tumor in the remaining cases was the upper lobe of the left lung in 3, the upper lobe of the right lung in 3, the lower lobe of the left lung in 3 and the lower lobe of the right lung in 1.

Histologically the postmortem specimens were characterized by necrosis and invasion. This necrosis was marked in lymph nodes and visceral metastases as well as in the primary growth. The epidermoid differentiation was varied in the different tumors and even in different sections from the same tumor, so that some

6, 4 and 3 might have been resectable at the time of postmortem examination. Overholt⁶ was able to show an operability of 22 per cent in all the cases in which he explored, and this percentage did not include the

Fig. 4 (case 6).—Postmortem specimen thirteen years after onset of symptoms. There were no extrathoracic metastases and no metastases to mediastinal lymph nodes. The carcinoma is epidermoid. Cancer surrounds the stem of the left bronchus.

areas appeared squamous cell in type while others tended to approach the oat cell type.

The spread of these tumors was definitely less than that usual for cancer of shorter duration. Extrathoracic metastases were demonstrated in only 3 of the 11 cases. One of the patients (J. C., in case 1) is still alive two years after a biopsy showing cancer in supraclavicular lymph nodes. Intrathoracic spread alone occurred in 7 additional cases. The pleura was involved in 2, the mediastinum (including the pericardium) in 4, the chest wall in 2 and the contralateral lung in 1. This spread probably appeared late in the course of the disease, since necropsy in cases 6 and 11 disclosed no spread beyond the lobe in which the tumor had arisen. Although the operability of such tumors is apt to be less in the stage seen at necropsy than in that observed at exploratory laparotomy, the tumor in cases 11, 10,

Fig. 5 (case 4).—Section through a broken down carcinoma: $\times 4$

cases in which a palliative resection might have been done; he found the tumor in 24 of 75 cases (32 per cent) operable when a histologic diagnosis was made.

6. Overholt, R. H., and Rumel, W. R.: Clinical Studies of Cancer of the Lung. J. A. M. A. (March 2) 1940.

On admission there were an abscess and empyema in 2 cases, an abscess alone in 2 and a broken down tumor simulating an abscess in 1. Pain, cough and wheezing were frequently the presenting symptoms in the remaining 6 cases, but when empyema or abscess occurred it so overshadowed the symptoms referable to a tumor that an underlying tumor was not even considered for several years. Bronchoscopic examination in 5 of the 6 cases of abscess did not result in a positive diagnosis of cancer. Only in case 6 was there visible evidence of encroachment on a bronchus, and even in this case a positive diagnosis was not made from bronchoscopic biopsy. The tumors were peripher-

overlies an early cancer. But when a pulmonary abscess is drained surgically, biopsy of its walls may show occult carcinoma. Lobectomy for some patients with abscess appears to be a logical procedure (case 4, figs. 3, 5 and 6).

Roentgenograms were not taken before the production of empyema and abscess except in case 4, in which a tumor the size of a golf ball was present. In the remaining 4 cases of abscess roentgen evidence of a tumor mass was not present until much later if at all; usually it was overshadowed by the empyema or the abscess. When the mass was seen it appeared round or oval. But in the roentgenograms of earliest peripheral pul-

Data on Eleven Men with Carcinoma

Case No.	Age	Duration of Carcinoma Until Diagnosis, Mo.	Duration from Diagnosis Until Death, Mo.	Total Duration, Mo.	Presenting Symptom of Disease	Location	Histologic Type	Treatment	Results of Biopsy and Postmortem Observations	Comment
1	53	60	24	84	Abscess, empyema, cough	Upper lobe of left lung, peripheral and circumscribed	Epidermoid	Drainage, irradiation	Biopsy of supra-clavicular lymph nodes positive for carcinoma	Patient alive 2 years after positive lymph node biopsy
2	48	42	12	53	Abscess, empyema, cough	Upper lobe of left lung, peripheral	Epidermoid	Drainage	Invasion through thoracic wall; no extrathoracic metastases	Death from sudden massive hemorrhage
3	46	38	0	96	Abscess	Upper lobe of right lung, peripheral	Epidermoid	Drainage	No extrathoracic metastases	Diagnosis not made until necropsy
4	45	24	4	28	Cough, pain, abscess	Lower lobe of left lung, peripheral	Epidermoid	Drainage, lobectomy and resection of chest wall and diaphragm	No extrathoracic metastases	Died after lobectomy with resection of chest wall
5	57	60	1	61	Abscess, cough, "pneumonia"	Lower lobe of left lung, peripheral	Epidermoid	Thoracotomy	Extension to pleura; no extrathoracic metastases	Died after thoracotomy of contralateral spontaneous pneumothorax
6	54	103	11	168	Pain, cough	Main stem of left bronchus, central	Epidermoid	Refused resection	Multiple peripheral abscesses; annular localized tumor	Bronchoscopic evidence of carcinoma 1 year before death
7	47	72	3	75	Pain, cough, dyspnea	Lower lobe of left lung, peripheral	Epidermoid	None	Widespread invasion of pericardium; death from chronic cardiac tamponade	Small pulmonary tumor
8	56	240	4	244	Pain, cough, wheezing	Upper lobe of right lung, central	Epidermoid	Irradiation, exploratory thoracotomy	Patient alive; mediastinal extension	Inoperable carcinoma
9	70	141	7	151	Wheezing, pain, cough	Upper lobe of left lung, peripheral	Epidermoid	None	Metastases to numerous mediastinal lymph nodes, also to spleen and liver	Death from massive pulmonary hemorrhages; cystic bronchiectases on left
10	68	120	1	120	Cough, dyspnea	Lower lobe of right lung, peripheral	Alveogenic	None	Spread to contralateral lung but no extrathoracic metastases	Death from bronchopneumonia
11	53	30	0	30	Cough, hemoptysis, dyspnea	Upper lobe of right lung, peripheral	Epidermoid	None	No extrathoracic metastases	Death from hemorrhage

ally located, beyond the range of the bronchoscope. The 5 patients without early abscess formation presented wheezing, pain and dyspnea as their earliest symptoms. The duration before diagnosis of symptoms referable to the thorax averaged ninety months. The duration from diagnosis until death or to the time of writing averaged only seven months. This indicates a long delay in diagnosis.

Why empyema and abscess occurred in 5 cases so long before the diagnosis was made is obscure. It is probable that the tumor in these cases arose near or in a small branch of the bronchus and tended to produce an abscess in a small area of lung in which bronchial drainage was obstructed and in which tension emphysema could develop. Rupture of the abscess, with resulting empyema, could have occurred easily in 2 cases. No clinical criteria were gained during this study that would make possible the diagnosis when empyema

monary carcinoma the shadow was irregular, small, and appeared moth eaten. Like bronchoscopic examination, roentgen examination does not prove the diagnosis in the majority of cases of peripheral tumor; thoracoscopy and exploratory thoracotomy are necessary. The use of microfilm and photofluorography offers a new method for detecting early peripheral pulmonary carcinoma in mass surveys before empyema and abscess have been produced.

Bronchoscopic biopsy showed positive evidence of cancer in cases 5, 7 and 8 only. This is a slightly lower percentage (27 per cent) than that of carcinoma in general, since of my 111 cases bronchoscopic biopsy gave positive results in approximately one third and in another third there was some evidence of tumor without corroborative biopsy. In cases 6 and 9 postmortem examination indicated that a corroborative biopsy specimen might have been obtainable.

The diagnosis in case 4 was based on biopsy of the abscess wall done at the time of surgical drainage. In case 1, in spite of surgical drainage biopsy of the peripheral abscess showed no tumor, and the diagnosis was not made until four years later, when a supraclavicular lymph node was found to be tumorous. In case 2 the tumorous tissue was obtained by transthoracic aspiration, which was later followed by extension through the chest wall at the site of puncture. In cases 3, 6, 10 and 11 the diagnosis was made at necropsy. Since the diagnosis was made late in the course of the disease in this group, in spite of bronchoscopic and roentgen examinations, it appears that newer knowledge and a newer approach are necessary before satisfactory surgical results can be obtained in a large percentage of cases.

Data on the 11 patients are presented in the accompanying table.

SUMMARY

1. Carcinoma of the lung may be of long duration; the duration from the time of onset of symptoms until diagnosis averaged ninety months in this series of 11 selected cases, 10 of which were epidermoid.

2. Of these cases evidence of spread of the tumor beyond the feasibility of surgical removal was present at necropsy in only 5, but a high operative mortality might have been expected at this late stage.

3. The delay in diagnosis was due to the inadequacy of bronchoscopy and roentgen examination to demonstrate early small peripheral tumors, particularly when empyema and abscess complicated them.

4. Exploratory thoracotomy to confirm the suspicion of cancer is a logical procedure and should be used as readily as is exploration for suspected abdominal cancer.

5. Lobectomy for abscesses of the lung possibly associated with carcinoma is a logical procedure, which should bring about removal of some early cancers when substituted for surgical drainage.

6. Education of both patient and physician is necessary to produce in them an anaphylactic reaction to the possibility of cancer in men over 40 with symptoms of pulmonary disorder.

REPORT OF CASES

CASE 1.—J. C., a white man aged 53, entered San Francisco Hospital in 1934 with symptoms of pulmonary abscess in the upper lobe of the left lung consisting of pleuritic pain, cough and the production of malodorous sputum. Two stage drainage for the abscess was performed on March 16 and 26, with removal of the second, third and fourth ribs. A large collection of encapsulated pus communicating with the bronchi was drained. The bacteria found in the pus were mixed, consistent with oral flora. Biopsy of the peripheral parietal and visceral pleura showed no neoplasm. Probable interlobar empyema from rupture of a peripheral pulmonary abscess was diagnosed. The patient was discharged May 15 with a bronchial fistula which was not completely healed until August. He remained well except for slight cough and minor infections of the respiratory tract until June 1938, when he noted an increase in the cough and some streaking of the sputum. In December he began to have pain over the left upper part of the chest, with radiation down the arm, along the distribution of the fifth cervical nerve. A lump appeared just above the middle of the left clavicle in March 1939. There was also a hard mass palpable beneath the left pectoral muscle. On May 29 a biopsy of the supraclavicular mass was performed. The mass was round and hard and was attached to all the structures in the vicinity of the brachial plexus and the scalenus anticus muscle. On removal of a small section (1 cm.) a large amount of sterile, pussy, necrotic material exuded from the mass. Histologic sections revealed metastatic carcinoma in a lymph node. Neutron

therapy, in a total dose of 525 neutrons, was given by Drs. Lawrence and Stone on June 6 and 20. Supervoltage roentgen therapy, with a force of 1,000,000 kilovolts, was administered August 3 to September 7. The skin-target distance was 80 cm.; the filter was 2 mm. of lead; the strength of the current was 1 milliamperes; the dose was 200 r measured in air to fields 15 by 15 cm.; the locality was the left upper part of the chest. Treatment was alternated anteriorly and posteriorly daily. The total dose to the front and the back was 3,000 r each. The size of the induration in the left supraclavicular area diminished rapidly, and the patient's general condition improved by October. Large veins appeared in the left anterior portion of the chest. Roentgenograms of the lungs indicated some diminution in size of the pulmonary opacity, but this was not extensive. On May 15, 1941, seven years after the pulmonary abscess and two years after the tumor was demonstrated in the supraclavicular lymph nodes, the patient was well and working. However, recent roentgenograms show a mass in the upper lobe of the right lung.

CASE 2.—W. McB., a white man aged 48, had empyema following "pneumonia" in 1935. Drainage of the empyema was performed, and the course was prolonged. A bronchial fistula closed after several months. About three and one-half years after the onset the patient reentered the San Francisco Hospital, where roentgenograms of the chest revealed in the upper lobe of the left lung a mass 3 to 4 cm. in diameter surrounded by shadows denser than normal. Bronchoscopic examination gave negative results. Transpleural aspiration resulted in a positive diagnosis of epidermoid carcinoma. The pulmonary mass slowly enlarged, and a supracostal mass appeared under the soft tissues of the chest wall in the region of the previous transpleural aspiration. The patient died of a sudden massive hemorrhage about one year after the diagnostic biopsy was made. The total duration of his illness was fifty-three months. Postmortem examination showed that almost the whole upper lobe of the left lung was replaced by a circumscribed epidermoid carcinoma. A large separate mass lay above the thoracic bony cage surrounding the upper lobe of the left lung. There was no massive invasion of the pleura.

CASE 3.—S. K., a white man aged 46, entered the San Francisco Hospital in 1934 with an acute, violent, putrid abscess of the upper lobe of the right lung. He was treated by conservative measures for five months. During this time bronchoscopic examination showed a severe inflammatory reaction but no evidence of neoplasm. The symptoms subsided, and he was discharged as cured, although roentgenograms still showed irregular opacities occupying the site of the abscess. Two and a half years after discharge he returned to the hospital with the history of having recently spat up bloody foul sputum. He was moribund on admission and died of acute necrotizing pneumonia. The total duration of symptoms was ninety-eight months. Postmortem examination showed diffuse pneumonia but showed also a localized epidermoid carcinoma in the upper lobe of the right lung. There were no metastases.

CASE 4.—J. V. H., a white man aged 45, had a history of cough, the production of sputum, loss of weight, dyspnea and intermittent hemoptysis for fourteen months. Intermittent fever was present, the temperature ranging from 100 to 101.5 F. The patient was hospitalized after extensive hemoptysis. After roentgen and bronchoscopic studies a diagnosis of probable pulmonary abscess was made. At bronchoscopy the tertiary branch of the bronchus in the lower lobe of the left lung was patent. Biopsy of a secondary division of this branch did not suggest bronchiogenic carcinoma. There was definite clinical improvement with conservative therapy, and the patient was discharged. Cough, the production of sputum and fever returned within one month, and after three months he was again hospitalized. Surgical drainage of the pulmonary abscess was then carried out. He continued to have hemorrhages from the wound and lost ground. After transfusions he improved somewhat, and about ten weeks after the original drainage an attempt was made to remove the lung. The lung was extensively adherent to the ribs and to the diaphragm. The patient died of shock, hemorrhage and bronchial obstruction before lobectomy and excision of the invaded thoracic wall could be completed.

(Jan. 15, 1941). Biopsy of the abscess wall in November 1940 had shown epidermoid carcinoma, and the postmortem examination showed that the "abscess cavity" was wholly composed of carcinoma. The total duration of symptoms was twenty-eight months.

CASE 5.—A. D. (a private patient of Drs. H. Brunn and Samuel Robinson), a white man aged 57, began to have pulmonary symptoms after an operation for jejunoileic fistula done with ether anesthesia. Approximately three weeks later a pulmonary abscess developed in the upper lobe of the left lung and was treated with medical measures, with subsequent subsiding of all symptoms and clearing of the shadow in the roentgenograms of the right lung. During the next five years he was well and free from cough except for occasional colds and "cigaret cough." His weight during these years increased from 135 to 190 pounds (from 61 to 86 Kg.). On Aug. 15, 1934 he had severe pleuritic pain on the left side and an increase of his cough, which was productive of purulent sputum. In the next two months the cough and production of sputum became progressively worse and the sputum was blood tinged. As the exacerbation had taken place in the Orient he immediately sailed for home. The condition was diagnosed as oriental pneumonia. Physical examination showed that his general condition was good. There were signs of dullness below the left scapula, and in the region below the scapular angle there were numerous coarse rales. There was no lymph adenopathy. The vital capacity was 1,800 cc. The blood showed mild anemia. The hemoglobin content was 85 per cent, the red cell count 5,140,000 and the white cell count 20,260, with 85 per cent polymorphonuclear leukocytes. Bronchoscopy on Jan. 20, 1935 showed an epidermoid carcinoma at the level of the division between the lower and upper lobes of the left lung. Exploratory thoracotomy was done on January 21. An inoperable carcinoma was found. No attempt at removal of the tumor was made. Postoperative subcutaneous emphysema occurred and terminated in bilateral pneumothorax. The patient died on the second day after operation. Roentgenograms made on January 17 showed atelectasis of the lower lobe of the left lung and slight displacement of the mediastinum to the left. Necropsy showed a carcinomatous mass in the lower part of the main stem of the bronchus, with atelectasis and abscess in the central portion of the mass in the lower lobe of the left lung. The pleura was invaded. The total duration of illness was sixty-one months.

CASE 6.—S. C., a white man aged 54, entered the San Francisco Hospital in 1936. The onset of symptoms was difficult to determine. In 1919 severe pleurisy on the left side was followed by cough. Since that time the patient had had a slight cough productive of mucoid sputum in small amounts. There were frequent recurrences of pleuritic pain until 1930. In 1933 the cough became worse, and in February 1936 it became more productive of grayish sputum. In May he began to have wheezing and dyspnea. He entered the San Francisco Hospital on Aug. 22, 1936 and was there for six months, during which he had continuous fever and a cough productive of mucoid purulent sputum, in varying amounts, of which examination was always negative for elastic tissue. He was discharged on Feb. 15, 1937 somewhat improved. In the next ten months he became worse. His cough increased, the sputum became more purulent and he lost 30 pounds (13.6 Kg.). He reentered the hospital on December 14. This time physical examination showed him to be emaciated and slightly dyspneic, but he did not otherwise appear acutely ill. Numerous rales were heard throughout the left side of the chest. Examination of the sputum was negative for tubercle bacilli, and roentgenograms showed atelectasis of the left lung. On Feb. 2, 1938 bronchoscopic examination showed incomplete stenosis of the bronchus in the upper lobe of the left lung, with an opening only $\frac{1}{16}$ inch (0.16 cm.) in diameter. Around this opening exuded thick purulent secretion, smears of which were negative for tubercle bacilli. Biopsy was not done at this time. The patient refused further therapy, and he died on Jan. 4, 1939. The total duration of symptoms was one hundred and sixty-eight months. Postmortem examination showed a localized annular carcinoma of the left lung, with stenosis of the main

stem of the left bronchus, atelectasis of the left lung, bronchiectasis and numerous secondary peripheral abscesses. Histologic examination showed the tumor to be epidermoid carcinoma.

CASE 7.—R. R., a white man aged 47, gave a history dating back about six years. There had been slight pain in the chest for years, but it had become much worse in the last one or two months. It was aggravated by coughing and deep inspiration, appeared about three hours after the patient ate and was worse after he ate meat. It was worse when he was on his back but was relieved by his leaning forward and by vomiting. There was substernal pain radiating to the back; this was burning and dull and lasted an hour or so. He had had a slight cough all his life, productive of a small amount of yellow mucoid sputum and worse in the morning (producing $\frac{1}{2}$ cup). There was no hemoptysis, but he showed dyspnea on exertion such as going up one flight of stairs and on lying on his left side. The patient was hospitalized for cardiac failure of undetermined cause June 29 to July 14, 1939 and has been compensated since. There were a slight lag, a diminished percussion note and breath sounds over the left side of the chest, with numerous moist rales. Roentgenograms of the chest showed a tumor of the lower lobe of the left lung. Bronchoscopy on Feb. 10, 1941 showed that the left bronchus was contracted and obstructed. Smears of material taken at the time of bronchoscopy were negative for acid-fast bacilli. Biopsy showed squamous cell carcinoma. The patient reentered the hospital in March 1941, and his course was steadily downhill until he died on April 10. The total duration of symptoms was seventy-five months. Postmortem examination showed an epidermoid carcinoma arising from the paramediastinal branch of the lower lobe of the right lung, with invasion of the pericardium and epicardium and the production of constriction of the heart. There were metastases to the pleura, lymph nodes, liver and small bowel.

CASE 8.—C. B., a white man aged 56, in 1921 had dry pleurisy on the right side followed by a dry, nonproductive cough. This was better in 1933. In June 1940 he noticed wheezing at night, particularly when lying on the right side. The cough became more constant and was paroxysmal after smoking. Night sweats were present intermittently for many years. Fluoroscopic examination in July 1940 showed a large density in the region of the right hilus. The sputum was mucoid, but examination was negative for acid-fast bacilli. Bronchoscopy on Feb. 21, 1941 showed an ulcerative stenotic lesion about the orifice of the upper lobe of the right lung. The pathologic diagnosis was epidermoid carcinoma. A severe injury to the right side of the chest with fracture of ribs had occurred in 1911. The Wassermann reaction was negative, although a diagnosis of syphilis had been made in 1911. The patient had smoked steadily since the age of 16, using one package of cigarettes daily. He had been exposed to chlorine fumes from a sewage plant during the past eight months. Roentgenograms made on July 27, 1940 showed a dense hilar mass on the right and upward displacement of the anterior part of the septum between the upper and middle lobes. There was probable atelectasis of the anterolateral segment of the upper lobe of the right lung. On Feb. 12, 1941 there was a noticeable diminution of the hilar density on the right. The anterolateral segment of the upper lobe of the right lung was aerated. On February 21 instillation of iodized oil showed that the upper lobe of the right lung failed to fill, although the middle and lower lobes filled readily. On March 12 exploratory thoracotomy was performed by Dr. A. L. Brown, and an inoperable tumor was seen. Several local metastases lay subpleurally, and there was one on the diaphragm. The growth had encircled the hilar vessels. The patient was advised to have high voltage roentgen therapy, which was performed in April. The total duration of symptoms to the time of writing has been two hundred and forty months.

CASE 9.—C. H., a white man aged 70, first entered the University of California Hospital on Oct. 21, 1928. There was a history of wheezing, and "asthmatic rales" were heard in the chest. Fluoroscopy gave negative results.

The symptoms recurred in 1935, with dyspnea, a definite sense of pressure in the chest and a cough productive of $\frac{1}{2}$ cup of mucoid sputum daily. There was an occasional pain of

pleuritic type in the left anterior part of the chest. In the last eight months before his second entry he became more dyspneic. There was no edema of the ankles or cardiac failure, but wheezing was present.

Physical examination on the second entry, on Nov. 19, 1940, showed signs of atelectasis or inflammation in the left upper part of the chest. Numerous rales, some bronchial, were present.

Bronchoscopy was performed on the day of admission and showed a distortion of the stem of the left bronchus with an upward displacement of the opening of the upper lobe of the left lung. No tumor was seen. Biopsy of a lymph node in the left supraclavicular region showed epidermoid carcinoma. Radiation therapy was not advised, and the patient was discharged. He remained in fairly good condition, without going downhill any farther, until May 16, 1941 (i. e. for six months), when he had a sudden massive pulmonary hemorrhage and died. Postmortem examination showed an epidermoid carcinoma which had excavated in the posterior portion of the upper lobe of the left lung and eroded its bronchus and a large pulmonary vessel in this region. There were metastases to several mediastinal lymph nodes and to the left pleura, one nodule in the liver and a huge cystic metastasis in the spleen measuring 4 inches (10.1 cm.) in diameter. There were no other gross metastases. Duration of symptoms referable to the thorax was one hundred and fifty-one months.

CASE 10.—L. R., a white man aged 68, began in 1930 to have dyspnea on exertion and a chronic slightly productive cough. These symptoms continued for many years, but he considered himself to be in good general health until July 1940, when after an infection of the upper respiratory tract he began to have progressively severe dyspnea and cough. The cough was productive of thin, yellowish, purulent material, blood-streaked every day. There was no loss of weight. Physical examination showed nothing remarkable except numerous tubal rales throughout both lungs. A roentgenogram of the chest in August 1940 showed a heavy, soft, irregular density overlying the lower posterior third of the right lung. In one area this looked like a beginning lung abscess. The patient died four days after entry. The duration of symptoms was one hundred and twenty months. The postmortem examination showed a diffuse carcinoma involving most of the alveoli of the lower lobe of the right lung, with lymphatic pleural involvement and spread to the left lung; the terminal illness was bronchial pneumonia. No distant metastases were present.

CASE 11.—H. M., an inmate of the California State Prison at San Quentin, had roentgenograms of his chest taken because of cough. A routine roentgenogram taken several years before had been negative for tuberculosis, the presence of which was never proved. The symptoms were minimal until the occurrence of hemorrhages which produced death. Serial roentgenograms showed a slowly enlarging tumor together with atelectasis of the upper lobe of the right lung. Death occurred after the illness had lasted thirty months. Postmortem examination showed in the upper lobe of the right lung a large epidermoid carcinoma which had not metastasized but which had obstructed the lobar bronchus.

ABSTRACT OF DISCUSSION

DR. EDWARD J. O'BRIEN, Detroit: This paper is interesting because carcinoma of the lung, existing as long as has been reported by Dr. Goldman, and not detectable with the bronchoscope, is most unusual. As a rule, malignancy of carcinoma is in inverse proportion to its proximity to the main bronchus. In other words, carcinomas detectable with the bronchoscope are less malignant than those located in the periphery of the lung. It is just such surveys as this, and those of Drs. Graham, Tuttle and others, that make the whole picture of carcinoma more confusing. It makes it more difficult to evaluate the results of any of our treatment. There is an ever increasing number of these patients who have had pneumonectomy performed and are still alive after five to seven years, but when we know that some live that long without anything being done, it is difficult to evaluate our results from surgery. About all that is known

about carcinoma of the lung is that it does exist and that, untreated, people will eventually die of it, and that radiation is in most instances only palliative. Pneumonectomy offers the only hope, and the picture following this procedure is not a bright one. In the hands of the best thoracic surgeons in this country and abroad, about 3 to 5 per cent of the patients who are seen and operated on can be salvaged. The immediate operative mortality ranges from 20 to 25 per cent. The picture is more dismal because early diagnosis is not made and I am afraid that, as much as we might hope for it, we never shall get a diagnosis of carcinoma of the lung as early as we do of carcinomas of the breast or the stomach. However, I would not like to give the impression of defeatism. Some can be salvaged. Without surgery, death of these patients is usually a pathetic one with much pain and discomfort. If the medical profession and the public would understand that the condition exists much more frequently than we used to think it did and that if it is found early we can offer some hope, our results in the future will be much better.

THE UTILIZATION AND EFFECT OF ADDED DEXTROSE

IN CASES OF CONTROLLED AND UNCONTROLLED DIABETES

JAMES A. GREENE, M.D.

AND

L. W. SWANSON, M.D.

IOWA CITY

There is a growing belief that diabetes mellitus is due to a variety of causes. According to one theory, there is a decreased ability to oxidize dextrose and, according to another, there is a disturbance in the liver which increases the output of dextrose. It was thought, therefore, that some cases may be due to the former and others to the latter cause. The administration of extra carbohydrate without added insulin to patients whose diabetes was controlled appeared to be a likely method of differentiating between the two possible types. The extra sugar should not be utilized by the patients who have a decreased ability to oxidize dextrose, whereas it may be utilized by those with disturbance of mobilization. For this reason the carbohydrate content of the diets of 56 patients whose diabetes was controlled and 36 whose diabetes was not controlled was abruptly increased, without an increase in the dose of insulin. Added sugar without extra insulin was administered to 3 depancreatized dogs whose diabetes was partially controlled. Lastly, 8 diabetic patients were studied in a metabolism chamber before and after the administration of extra sugar. The results of these observations are the subject of this report.

EFFECT OF ADDED CARBOHYDRATE ON CONTROLLED DIABETES

The ages of the 56 patients ranged from 15 to 81 years. The quantity of added sugar varied from 20 to 260 Gm., averaging 100 to 150 Gm. daily, and it was administered for from one to one hundred and one days, the period of administration averaging five to ten days. It is to be noted from table 1 that 55 patients utilized the added sugar. The diabetes was moderate to severe in most instances, and the different age groups were adequately represented. Of the 55 who utilized the

added sugar, 18 showed improvement of the diabetic condition, as evidenced by reduction of the dose of insulin within one to fourteen days by from 5 to 25 units. The severity of the diabetes and the age distribution of the patients who improved are shown in table 2. The 1 patient who did not utilize the added sugar was a white woman aged 79 who five months previously had required 75 units of insulin with a diet containing 150 Gm. of potential dextrose. The diabetes improved, until she was aglycosuric with a diet containing 350 Gm. of potential dextrose and without insulin. The addition of 100 Gm. of carbohydrate to this diet resulted in the excretion of from 7 to 22 Gm. daily.

EFFECT OF ADDED CARBOHYDRATE ON UNCONTROLLED DIABETES

The improvement of the diabetes in some of the cases mentioned suggested that added sugar may aid in freeing the urine of sugar in certain cases in which the diabetes is difficult to control. Carbohydrate in amounts of from 100 to 300 Gm. daily was added, therefore, to diets of 36 patients whose urine contained sugar, because the disease was difficult to control in most instances. It will be noted from table 3 that 35 patients utilized the added sugar and that the different age groups were adequately represented. The urine promptly became free of sugar in 15 instances, and in several the insulin was reduced. The age distribution of these patients and the severity of the diabetes are shown in table 4. The diabetes of the 1 patient who did not utilize the added sugar was not difficult to control. She was a white woman aged 71 whose diabetes had been controlled with an estimated diet and small amounts of insulin. She was given a diet containing 270 Gm. of potential

blood sugar level. A uniform response was not observed. There was an increase in the blood sugar level in 9 cases, in 2 it increased and then declined, in 5 it was not altered and in 13 it declined, as noted in table 5.

EFFECT OF ADDED CARBOHYDRATE ON DEPANCREATIZED DOGS

It has been considered by some investigators that the addition of sugar in cases of diabetes stimulates the pancreas to secrete more insulin. To ascertain whether

dextrose, and the insulin was omitted. Glycosuria appeared, and after the addition of 200 Gm. of carbohydrate to this diet the daily urinary dextrose was increased by 14 to 20 Gm.

EFFECT OF ADDED CARBOHYDRATE ON BLOOD SUGAR LEVELS

A sufficient number of blood sugar estimations two hours after breakfast were obtained in 29 cases to ascertain the effect of the added carbohydrate on the

or not this was the entire mechanism for the utilization of the extra sugar, 50 Gm. of cane sugar was added to the diets of 3 depancreatized dogs whose diabetes was partially controlled by insulin. The utilization of the extra sugar by these animals without added insulin as noted in table 6 excludes the stimulation of the secretion of insulin as the only mechanism for the utilization of the added carbohydrate.

STUDIES OF PATIENTS IN METABOLISM CHAMBER

Eight patients were studied in the metabolism chamber to ascertain the amount of dextrose oxidized when their usual diet and dose of insulin were taken and again after the administration of 50 to 70 Gm. of extra carbohydrate. The amount of extra sugar oxidized varied from 3 to 17.9 Gm. for a four hour period, and the amount oxidized was not related to the age of the patient or to the degree of severity of the diabetes, as shown in table 7.

COMMENT

It is not our purpose to enter into the controversy regarding the use of high carbohydrate diets in the treatment of diabetes mellitus. The addition of carbohydrate to the diet of patients with diabetes mellitus was not of value in the differentiation between the different types of diabetes, if such exist.

The utilization of higher carbohydrate diets without added insulin has been observed by several authors including Sansum, Blatherwick and Bowden,¹ Richard-

improvement in tolerance produced in the diabetic patient by administration of extra sugar and extra insulin by Gibson¹¹ and Ellis¹² and the studies of Adlersberg and Porges,⁷ Sweney¹³ and others suggest an increased insulin secretion. That this explanation is not entirely adequate is shown by utilization of the extra sugar by the depancreatized dogs.

It appears, therefore, that some other mechanism is involved. Adlersberg and Porges⁷ thought that the storage of glycogen in the liver was an important factor. Ellis¹² suggested that depletion of the sugar stores of the body played a role. Chambers¹⁴ has recently reviewed the subject of the influence of undernutrition in carbohydrate metabolism. It has been shown that the maximum utilization of administered dextrose is found in the normal person when carbohydrate has been supplied abundantly in the diet. The utilization of

dextrose diminishes as the carbohydrate intake is reduced. We¹⁵ have recently shown that the diminished dextrose tolerance curves observed in certain endocrine diseases could be improved by high carbohydrate diets and then diminished by low carbohydrate high fat diets. Most patients with diabetes mellitus have been losing a considerable amount of sugar through the urine by the time the physician is consulted; therefore the sugar stores have been depleted to varying degrees, and there has been a high fat content of the metabolic mixture. It is possible, therefore, that these patients have not only diabetes but in addition a further diminished ability to utilize dextrose secondary to this partial depletion of sugar.

The results of the metabolic studies indicate that there was depletion of sugar in our cases. Three of the patients studied were typical of the patients who received added carbohydrate to their diets. These patients (3, 4 and 7 in table 7) utilized the added 50 and 70 Gm. of sugar without glycosuria, whereas patients 2, 5, 6 and 8 were selected because it was thought that there was no depletion of sugar. Their diabetes had been controlled for several weeks to months prior to study and glycosuria appeared following the addition of sugar. The longer the diabetes had been controlled the greater was the glycosuria. Patients 5 and 8 had been controlled for more than a year and they excreted 12 and 21 Gm. of the added sugar, whereas patients 2 and 6 had been controlled only a few weeks and they excreted 6 and 8 Gm. of the added sugar. The utilization of most of the carbohydrate added to the diets of our patients appears, therefore, to have occurred by deposition into the sugar stores of the body. The improvement in the diabetes as evidenced by the reduction of insulin requirement or by prompt disappearance

of sugar from the urine was due probably to correction of the existing sugar depletion. This mechanism does not explain the fact that patients in whom the sugar stores are not depleted will utilize most of the sugar added to their diet.

We have considered it advisable routinely to administer a higher carbohydrate diet for a few days after the urine has been rendered free of sugar in order to correct

the existing sugar depletion. The length of time necessary to correct this depletion is not known. It undoubtedly varies in different cases. It required from six days to six months of diet for alteration of the dextrose tolerance curve in some of our cases of hypoglycemia.¹⁶ It is for the same reason in our opinion advisable to administer extra carbohydrate to patients with diabetes which is difficult to control or which is unstable. It is not our opinion that all cases of unstable or difficult to control diabetes are due to sugar depletion, but the diabetes in certain of these patients will become more easily controlled or more stable as the existing sugar depletion is corrected.

It is generally agreed that with an increased metabolic rate there is a greater demand for dextrose. In cases of diabetes mellitus and hyperthyroidism the greater requirement for dextrose will decrease the sugar stores of the body unless the carbohydrate intake is increased. In such cases we have found it advantageous to increase the carbohydrate content of the diet by from 100 to 250 Gm. daily and in most instances the insulin requirement is not increased. A typical illustration is the following case.

A white girl aged 17 years has diabetes and hyperthyroidism. The diabetes was controlled with a diet containing 200 Gm. of potential dextrose and 65 units of insulin daily. The diet was abruptly increased by 300 Gm. of carbohydrate without an increase in the dose of insulin, and the urine remained free of sugar. The insulin requirement gradually decreased 25 units in seventeen days.

There is likewise a greater demand for dextrose during an infection with or without a systemic reaction, and unless the carbohydrate content of the diet is increased the sugar stores of the body will be reduced in proportion to the increased demand. In such cases the addition of extra carbohydrate to the diet will not increase the insulin requirement or will make any increase in requirement due to the infection comparatively less than would be necessary without the added sugar. The patient thereby utilizes a greater amount of dextrose with less insulin. This point is illustrated by the following case.

A white woman aged 48 years had had diabetes for several years which had been controlled with 45 units of insulin daily and a diet containing 150 Gm. of potential dextrose. A severe infection of the hand developed and by the time of admission to the hospital the insulin dosage had been increased to 75 units daily. In spite of this increase in insulin dosage the urine continued to show sugar. The addition of 100 Gm. of carbohydrate to her diet was followed promptly by disappearance of sugar from the urine. There was no apparent improvement in the infection until five days later, following extensive incisions of the hand.

From our previous experience with similar cases the insulin requirement would have increased to approximately 100 or more units daily. Under such circumstances the patient could not have utilized much over 150 Gm. of potential dextrose. The added carbohydrate, however, permitted her to utilize 250 Gm. of potential dextrose with less insulin.

The influence of addition of extra carbohydrate to the diet on the blood sugar level in certain cases is illustrated here:

A white man aged 67 years has diabetes mellitus and arteriosclerotic gangrene of the leg. The diabetes was controlled with

10 units of insulin and a diet containing 170 Gm. of potential dextrose. The blood sugar level two hours after breakfast gradually increased to 397 mg. per hundred cubic centimeters. The addition of 100 Gm. of carbohydrate to the diet reduced the blood sugar to 133 mg. per hundred cubic centimeters by the fourth day; the leg was not amputated until two days later.

SUMMARY

Carbohydrate was added to the usual regimen of patients with controlled diabetes in an unsuccessful attempt to differentiate between possible types of diabetes. Only 1 of the 56 patients failed to utilize the added sugar, whereas 18 required less insulin. Since such an improvement indicated a beneficial effect, extra carbohydrate was added to the diets of 36 patients with uncontrolled diabetes. Only 1 failed to utilize the added sugar, whereas the urine of 15 promptly became free of sugar. There was no uniform response of blood sugar levels.

Studies on patients in the metabolism chamber and on depancreatized dogs show that neither oxidization of the added sugar nor increased secretion of insulin explains the utilization of the added carbohydrate.

It is postulated that depletion of the sugar stores of the body further reduces the ability of many diabetic patients to utilize dextrose and that the correction of this depletion improves the diabetes in such cases.

ABSTRACT OF DISCUSSION

DR. H. O. MOSENTHAL, New York: I desire to confine my remarks to the empirical results of augmenting the starches in the diet. This may prove to be advantageous in treating diabetic patients, especially those resistant to insulin. Apparently through the use of insulin a change has been wrought in the diabetic so that they may respond favorably to increased amounts of carbohydrate. This was not the rule but the exception in the preinsulin days. With the use of insulin, apparently a certain reserve for the utilization of sugar is built up which responds to the stimulus of added carbohydrate by increasing the dextrose tolerance. Without insulin the same occurs in normal persons, but this is not true of untreated patients with diabetes. Dr. Anna Spiegelman and I have recently carried through some experiments which show that, in mild diabetes in which insulin is not required, in some a low carbohydrate diet may serve to build up tolerance, while in others an optimal diet which may vary from 150 to 400 Gm. of carbohydrate intake may serve that purpose. What seems to me particularly significant is the result obtained in cases of infections and hyperthyroidism. In these states characterized by more or less insulin resistance the effectiveness of insulin can be enhanced according to Greene and Swanson by the giving of high carbohydrate diets. The principle of satisfactory utilization of added dextrose in cases of both controlled and uncontrolled diabetes and of insulin resistant cases can be hailed as a step forward in the management of diabetes. There is no set diet which is most advantageous for any diabetic patient and it is a matter of trial and error to determine what shall be most beneficial. Diets low in carbohydrate are successful in controlling the carbohydrate metabolism of obese diabetic patients, higher carbohydrate diets are established as the most advantageous for growing children and for the manual laborer, while medium carbohydrate diets containing 130 to 150 Gm. of starch are usually considered most suitable for sedentary workers.

DR. DAVID ADLERSBERG, New York: I would like to compliment Drs. Greene and Swanson on their interesting paper. Dr. Greene was kind enough to quote the work that Porges and I did years ago on the same subject. Experiments of this type, with addition of dextrose or other carbohydrates to the diet of normal and diabetic persons, with or without insulin, were the first steps which eventually led to the introduction of high carbohydrate diets in the treatment of diabetes. One of

arsphenamines has been reported.¹¹ Of these, 118 patients, or 88.1 per cent, were able to tolerate mapharsen in therapeutic doses.

Jaundice as a complication of mapharsen therapy was reported in some of the series.¹² Among 10,370 patients, one of every 450 had jaundice during therapy. The jaundice was mild and disappeared within three to eight weeks.

TABLE 1.—Fatalities Following Mapharsen Therapy

Rein and Wise ¹⁶	1939	♀	32	Mapharsen, 5	Granulocytopenia
		♀	70	Mapharsen, 20	Aplastic anemia
Kirkham and Perlmutter ¹⁵	1941	♀	24	Mapharsen, 20	Aplastic anemia

Blood Dyscrasias.—Five mild reactions were reported, three of purpura and two of "involvement of the hemopoietic system."¹³

Epstein and Falconer¹⁴ stated that mapharsen has serious potentialities for injuring the bone marrow. One patient had a "so-called aplastic anemia after five doses of mapharsen. She had a well marked anemia before mapharsen was given and undoubtedly her bone marrow was vulnerable."

Three fatalities were reported,¹⁵ two from aplastic anemia and one from agranulocytosis.

The hemopoietic toxicity resulting from mapharsen apparently is somewhat different from that resulting from neosarsphenamine. Mapharsen may be tolerated after neosarsphenamine has produced profound toxic effects. Seven patients with thrombocytopenic purpura,¹⁶ 1 patient with purpura but no reduction in platelet count¹⁷ and 2 patients who recovered from granulocytopenia¹⁸ as reactions to neosarsphenamine showed no signs of toxicity when mapharsen was given.

Nephrosis.—Some reports indicate that subclinical mild kidney damage may occur during mapharsen therapy.¹⁹ Examination of the urine showed such evidence in 9 of 597 patients, a ratio of 1:64. Howles²⁰ reported that 1 patient with acute nephrosis had congenital syphilis and received concurrent mapharsen and bismuth therapy. Mapharsen is not especially nephrotoxic, although two deaths due to kidney damage were attributed to its use.²¹

Vasomotor Reactions.—It is difficult to state whether or not any true nitritoid reactions are caused by mapharsen. There are reports of 15 cases in which vasomotor reactions occurred.²² These reactions were described as "abdominal cramps, generalized aching, flushing and rapid pulse"; "shock, pallor, weakness, nausea and vomiting"; "vascular crises closely resembling a 'nitritoid'"; "headache, general malaise, high fever." It may be inferred that no true nitritoid reaction has been described in the literature. It is interesting to note, however, the reports of 42 cases in which there were severe, repeated nitritoid crises from the arsphenamines.²³ These patients tolerated mapharsen without any reaction resembling a nitritoid crisis.

Miscellaneous Reactions.—A large group of miscellaneous reactions was reported by various authors.²⁴ These were vertigo, headache, chills, lacrimation, salivation, chest pain and pain in the teeth and gums. Locally venous spasm and pain in the arm were noted.

Toxic Effects of Mapharsen as Compared to Neosarsphenamine Which Occur During Massive Arsenotherapy by the Continuous Intravenous Drip Method.—The observations already recorded indicate that mapharsen is less toxic than neosarsphenamine when

cent had some form of dermatitis, a complication which developed in only 11 per cent of 288 patients who received mapharsen. One case of exfoliative dermatitis occurred after administration of neoarsphenamine, none after mapharsen. Jaundice occurred in 3.6 per cent of the patients who received neoarsphenamine and in 0.7 of those who received mapharsen. A high incidence of peripheral neuritis, 35 per cent, occurred with neoarsphenamine but only 1.6 per cent with mapharsen. One case of hemorrhagic encephalitis occurred in each group; the 1 due to neoarsphenamine was fatal.

Death Rate from Mapharsen.—Two of the 6 cases in which deaths occurred were published as single case reports. The remaining four deaths occurred in a series of 15,752 patients. The ratio is one death among 3,938 patients. The total number of injections accounted for in this review of the literature is 269,326. The ratio is one death to 67,332 injections. It should be noted that the 269,326 injections represent only about 2 per cent of the amount of mapharsen that had been distributed. If it is assumed that all the manufactured doses had been given, and if only six deaths occurred, then the lowest possible rate is one death to two million injections.

Mapharsen and Neoarsphenamine.—Any significant comparison of the toxicity of these two drugs should be made in groups of similar patients given the same routine treatment. Therefore the reports of the United States Navy on the treatment of young, comparatively healthy males is of value (table 2). Neoarsphenamine definitely is the more toxic. There were no deaths following 121,689 injections of mapharsen, whereas forty-nine deaths followed 1,301,913 injections of neoarsphenamine.

The death rate, according to the literature, is one to 67,332 injections of mapharsen. This is less than one half the death rate from neoarsphenamine.

CONCLUSIONS AND SUMMARY

1. A review of the literature shows that mapharsen is less toxic than neoarsphenamine.

2. To date only six fatalities from mapharsen have been reported. This rate is remarkably low considering that over twelve million ampules of mapharsen have been manufactured. The deaths were reported as due to kidney damage in 2 cases, hemorrhagic encephalitis in 1, aplastic anemia in 2 and acute agranulocytosis in 1.

3. Patients who have mild or moderate cutaneous reactions to the arsphenamines usually (in about 85 per cent) can tolerate mapharsen. However, those who have true exfoliative dermatitis almost always (in 90 per cent) react similarly to mapharsen. It is probably not justifiable, then, to use mapharsen for a patient who has had a severe exfoliative dermatitis from arsphenamine. A mild or moderate degree of dermatitis does not contraindicate the trial of mapharsen when arsenicals are deemed essential.

4. About 90 per cent of the patients who have severe gastrointestinal reactions to the arsphenamines can tolerate mapharsen in therapeutic doses.

5. Symptoms suggestive of nitritoid reaction have been reported but no case of true nitritoid reaction from mapharsen has been described. It is interesting to note that 42 patients who had severe nitritoid reactions from the arsphenamines were able to tolerate mapharsen without difficulty.

6. Toxidermia was noted in about 1.5 per cent of 13,769 patients who had received 240,811 injections of

mapharsen. The incidence of exfoliative dermatitis in this group was 0.11 per cent. Not one of these was fatal.

7. Seven patients with thrombocytopenic purpura and 2 patients with granulocytopenia from neoarsphenamine were able to tolerate mapharsen without reaction. Mapharsen may occasionally cause severe damage to the hemopoietic system.

8. Careful observation of the use of mapharsen and neoarsphenamine by the intravenous drip method showed that mapharsen causes fewer and milder toxic reactions than neoarsphenamine.

9. The United States Navy statistics on observations of reactions to neoarsphenamine and to mapharsen among patients comparable as to age, sex and general condition of health indicate that mapharsen is definitely the less toxic.

GLOBULIN FRACTIONS OF A AND B AGGLUTINATING SERUMS FOR BLOOD TYPING

A RAPID CARD TECHNIC FURNISHING A PERMANENT RECORD

WILLIAM THALHIMER, M.D.

AND

SOPHRONIA A. MYRON, A.B.

NEW YORK

It is well known that it is difficult to secure large amounts of high titered A and B serums for determining blood groups. It is especially difficult to secure satisfactory A serum.

Since it has been demonstrated that antibodies can be concentrated by various methods of globulin fractiona-

tion, globulin fractions were prepared of pooled type A and pooled type B serums in the attempt to concentrate these specific isoagglutinins. It was felt that if this could be accomplished it would not be necessary to secure high titered agglutinating serums from the small percentage of individuals who yield these, but the agglutinins could be concentrated sufficiently in the globulin fraction from pools of low titered serums.

It has been found, as the study progressed during the past two years, that it was extremely easy to accomplish this.

One or two liter pools were prepared, and the agglutinin titer of each individual serum, as well as that of the unconcentrated pool and the globulin fractions¹

1. Mr. Eugene Cardone, of the Bureau of Laboratories, New York City, prepared these globulin fractions.

which resulted, was determined by Davidson's technic.² At times we purposely worked with serum of a very low titer; at other times we made pools of ten or more serums as we obtained them and determined their titer later, along with that of the unconcentrated pool and the globulin fraction. The last two pools prepared may serve as an illustration, and these results are given in the accompanying table (tables 1 and 2). The agglu-

Several hundred individual type A serums have been tested, and the titer has been found to vary from 1:7 to 1:448

tinating titers of some of the globulin fractions were found to be quite high, up to 1:3,584 (table 3). However, some extremely efficient globulin fractions had only a moderately elevated agglutinating titer. The final criteria of the test are the rapidity with which macroscopic agglutination appears and the size of the clumps. There has been no difficulty in preparing fractions which will show easily detectable agglutination in five seconds or less, and within twenty to thirty seconds large clumps will have formed. There is a general trend of correlation of the titer of the isoagglutinins and the rapidity of macroscopic agglutination, but the correlation is not exact. The two globulin fractions, numbers 14 and 15, are just as rapid and reliable as others with higher agglutinin titer.

At different times ammonium sulfate and sodium sulfate precipitation of the globulin has been carried out. The results indicate that a better preparation with better keeping qualities results from sodium sulfate precipitation.

The globulin fraction is concentrated four or six times the original pooled serum. To some fractions 0.25 per cent phenol and 1:20,000 merthiolate were added, and others were prepared without preservative. Both were found satisfactory. The preparations were clarified by passing through a Buchner funnel containing paper pulp and filtercel, and then through a clay filter which holds back bacteria. The final preparation is placed in vials, is clear and has very much the appearance of

slightly concentrated serum. This sterile, vialled material has not deteriorated when kept in a refrigerator at plus 5 C. for at least six months.

METHOD OF DETERMINING THE BLOOD TYPE

A drop of type A serum and a drop of type B serum are placed on a card.³ These drops should be about 5 mm. in diameter. The blood used in the test is obtained from the patient's finger. Place a drop of blood about 2.5 mm. in diameter next to each drop of typing serum. Mix thoroughly with a toothpick, spreading the mixture to a circle about 1.5 cm. in diameter. Rotate the card slowly until maximum agglutination has occurred and then allow the drops to dry.

Blood groupings carried out in this manner shown in the illustration, furnish a permanent record which can be attached to the history sheet. The mixture of blood and serum absorbs slightly into the paper and this film is almost impossible to remove from the paper when completely dry.

The blood grouping serums may be differentiated by adding aqueous methylene blue to the B serum and eosin to the A serum.

Since drops of serum can be dried on a card and redissolved with water or physiologic solution of sodium chloride at the time of performing the test, a study was made of how long the drops of dried serum could be relied on. It was hoped that the dried serum would retain its specific efficiency for a long period. Some of the cards with dried serum on them were kept at room temperature, some in the icebox and some in the thermostat. Unfortunately, it was found that the efficiency of the dried serum could not be relied on for longer than three to seven days. It might be that if the cards of dried serum were kept under special conditions in an oxygen free atmosphere and perhaps in the icebox, the

Several hundred individual type B serums have been tested, and the titer has been found to vary from 1:28 to 1:3,584.

efficiency would last longer. Even if this occurred, it would not be practical for routine use.

However, these A and B globulin fractions have been dried out of the frozen state in vials and this dried

3. The idea for performing this test on cards or paper suggested itself to one of us when Dr. M. Ruiz Castaneda demonstrated his technic of the Weil-Felix agglutinating test for typhus fever in his laboratory in Mexico City. Dr. Castaneda places a large drop of a heavy suspension of killed proteus X organisms, suspended in a solution of methylene blue, on a piece of glazed paper, and adds to that a large drop of the patient's blood obtained from a finger prick. These are mixed rapidly and in the positive cases agglutination occurs rapidly. The blue stained clump stands out sharply on a slightly pinkish blue background.

2 Davidson, Israel: Test for Infectious Mononucleosis, *Am J Clin Path.* Tech. Supp. 2: 56 60 (April) 1938.

material has proved entirely satisfactory. A small amount of this dried powder, making a small mound 4 or 5 mm. in the base and about 2 mm. high, is placed on the card and one or two drops of distilled water added to it. These are mixed with a toothpick and the powder readily dissolves in not more than a minute. The test is then carried out as described. Some of this material has been kept at room temperature in a bottle filled with atmospheric air for several weeks and has shown no deterioration. The dried material has been redissolved in the vial by adding distilled water and has proved satisfactory.

The preparations are equally reliable when used on glass slides with dilute suspensions of blood or cells for the usual microscopic tests. In fact, dilution of the globulin fraction to one half with physiologic solution of sodium chloride at times produces an even sharper microscopic agglutination.

SUMMARY

This study has demonstrated that blood group specific isoagglutinins for determining blood types can be greatly concentrated by the usual method of globulin fractionation with sodium sulfate. When the globulin fraction is prepared from the usual low titered serums encountered, concentration from four to six times of the

TABLE 3.—*Agglutinating Titers of Globulin Fractions Before and After Concentration*

filtered sterile globulin solution yields a clear preparation which is completely satisfactory and reliable for either macroscopic or microscopic determination of blood groups.

Preparations are easily obtainable which show detectable macroscopic agglutination of red cells in five seconds, with the formation of large clumps in twenty to thirty seconds. The macroscopic test can be carried out on the usual type of filing card or on paper which is not too porous. The tests are easy to read when still in the wet state, both positives and negatives being clearcut. When allowed to dry, the negative tests sometimes assume a finely granular appearance, which, after experience, should be easily differentiated from the positive tests.

Tests can be allowed to dry, after which the cells adhere with tenacity to either the paper or the card and can be rubbed off only with great difficulty. Therefore the original test can be kept as a permanent record with the patient's history.

Instruction for performing the test can be printed on large cards or history sheets with a diagram for determining each of the four groups. With but little demonstration, interns and technicians can easily learn to carry out this test at the time of the original physical examination of the patient, and this can be filed with the patient's history as a permanent record of his blood type.

Clinical Notes, Suggestions and New Instruments

STREPTOCOCCUS VIRIDANS SEPTICEMIA

A CURE WITH SULFAPYRIDINE

GEORGE B. MOORE JR., M.D.

Major, M. C., U. S. Army

AND

A. J. TANNENBAUM, M.D.

First Lieutenant, M. C., U. S. Army

CAMP CLAIBORNE, LOUISIANA

As time goes by in this sulfonamide era it becomes increasingly obvious that a vast, ever increasing field in the future realm of therapy lies not in the operating room but in the chemistry laboratory, where the transmutation of metals is as naught compared with the evolution of ideas as they pass through the crucible of new interpretation. The case to be presented is one of *Streptococcus viridans* septicemia, proved by four positive blood cultures. The patient was discharged from the hospital cured, as evidenced by six negative blood cultures and by normal physical and laboratory examinations.

REPORT OF CASE

E. A., aged 20, a private in Battery F, 125th Field Artillery, 34th Division, whose general health had always been excellent, entered the Station Hospital, Camp Claiborne, Louisiana, on March 14, 1941, complaining of "flat feet." Two days later, during convalescence from a mild nasopharyngitis, there was an elevation of temperature to 100 F., a white blood cell count of 10,000 and constant pain over McBurney's point. An acutely inflamed, nonsuppurative appendix was removed through a McBurney incision under spinal anesthesia augmented by ether inhalation. Convalescence was progressing uneventfully until the third postoperative day, when pleurisy and bronchopneumonia developed in the lower lobe of the right lung. This diagnosis was confirmed by roentgenograms. The patient was given sulfathiazole 4 Gm. immediately, then 1 Gm. every four hours for the next forty-eight hours, at the end of which time he complained of severe pain precordially and in the left shoulder. Inspection of the chest revealed a bulge in the left parasternal region, over which a to and fro grating sensation was detected on palpation and a loud rough sound on systole and diastole transmitted to the left axilla and posteriorly to the angle of the left scapula on stethoscopic examination. Valvular sounds could not be evaluated because of extreme precordial noises. The blood pressure was 100 systolic and 80 diastolic. Percussion revealed the left border of the heart to extend to the left anterior axillary line. Retromammary dullness measured 8 cm. A 6 foot heart plate was confirmatory for pericardial effusion. The cardiothoracic ratio was 67. The electrocardiogram revealed low voltage in all QRS complexes and barely positive T₁ and T₂, with an isoelectric T₃. A blood culture was taken. Two days later T₁ and T₂ were negative, T₃ isoelectric and T₄, which previously had been positive, was now also negative.

Five days after the onset of the pericarditis the blood culture revealed a growth of *Streptococcus viridans* hemolyticus. The blood pressure was 102 systolic and 58 diastolic and numerous red, slightly cyanotic, raised patchy areas measuring 2 by 2 cm. appeared within four days. There were no small cutaneous petechiae. No retinal hemorrhages were present. Blood cultures were taken every other day until four had been taken.

On the sixth day after the onset of precordial distress the patient had a severe shaking chill followed by a temperature of 102 F. Urinalysis revealed the presence of white blood cells, red blood cells, albumin 3 plus and granular and cellular casts. The abdomen became noticeably distended and necessitated the use of intramuscular pitressin. The pericardial grating was diminishing to the point at which a long, soft blowing systolic murmur became audible over the entire precordium, and P₂ was definitely accentuated. All four blood cultures were now reported positive for growth of *Streptococcus viridans*.

From the Station Hospital.

and it was decided to administer sodium sulfapyridine intravenously. Six Gm. of this drug in 150 cc. of sterile distilled water was carefully, cautiously and extremely slowly administered by vein twice a day in addition to 1 Gm. by mouth every four hours. The general condition of the patient was extremely poor and he was given supportive treatment with whole blood, dextrose and physiologic solution of sodium chloride. The patient received this chemotherapy for four days, the blood pyridine concentration being raised to 16 mg. per hundred cubic centimeters. After this his temperature range was within normal limits except for an occasional slight elevation. He had no further chills. Urinalysis revealed but few red blood cells. Daily ophthalmoscopic examination revealed normal fundi. The spleen was not palpable. Six blood cultures taken from this point on were subsequently reported sterile. The pulse rate continued at a rate of 120 a minute. A short, systolic, apical murmur was audible, and P_2 was considerably decreased in intensity. There were frequent premature ventricular contractions.

In spite of roentgen and physical evidences of the heart and lungs having returned to normal, the electrocardiographic readings were more gradual in their return to normal. Ten weeks after the initial onset of the disease all laboratory and physical examinations except the blood sedimentation rate had returned to normal. The sedimentation rate was still 26 mm. in the first half hour. This reverted to 4 mm. in the eleventh week and remained so on three subsequent examinations. The patient has gained 50 pounds (22.7 Kg.) and has no further complaints, complications or sequelae. There was no pronounced anemia such as that produced frequently in these cases by the powerful streptococcic hemolysins.

SUMMARY

This case shows how decisive must be the action of the chemotherapeutic agent sulfapyridine on *Streptococcus viridans* in the blood stream. Four positive blood cultures prove conclusively that the blood stream was infected and then, after the blood sulfapyridine concentration was raised to and maintained at 16 mg. per hundred cubic centimeters for four consecutive days, the subsequent blood cultures remained sterile.

For several days in the early stages of this illness there was every reason to believe that we were dealing with endocarditis as well as pericarditis as a complication in this case.

The case illustrates forcefully how critically and how desperately ill a patient with this type of condition can be and yet make a 100 per cent recovery, as revealed by the fact that examination six months after the onset of illness reveals no abnormal physical or laboratory findings.

CEREBRAL DAMAGE FROM INSULIN "SHOCK"

HEMIPLEGIA, APHASIA AND EPILEPTIC SEIZURES
FOR FIFTEEN MONTHSFRANK N. ALLAN, M.D., BOSTON, AND R. M. CROMMELIN, M.D.,
PORTLAND, ORE.

Symptoms occurring from overaction of insulin in the treatment of diabetes usually disappear so quickly and so completely that they are now regarded with little concern. Even coma and convulsions no longer cause alarm. In fact, the production of convulsions in insulin therapy of mental disease is undertaken deliberately in the hope of securing beneficial effects. Yet it should not be forgotten that hypoglycemia may cause death or permanent disability from damage to the brain.

A number of reports have been published concerning such results in cases of spontaneous hyperinsulinism as well as in mental and diabetic cases in which insulin therapy has been given.¹ At the same time it must be pointed out that evidence

of permanent harm to the central nervous system has been encountered with relative rarity, considering the large number of diabetic patients treated daily with insulin. Textbooks on diabetes cite isolated examples. Joslin and his associates² mentioned suspicion of permanent mental change after a severe insulin reaction in 1 case, but the origin was not certain in view of previous mental instability and alcoholism. Wilder³ described a case which was also included in the previous report by Layne and Baker; a boy had permanent mental deterioration after a severe insulin reaction which caused unconsciousness lasting six weeks.

A case of juvenile diabetes, seen at the Lahey Clinic, illustrates the unfortunate consequences of cerebral damage from insulin "shock." It is also unique in that epileptic symptoms occurred for fifteen months after recovery from hypoglycemia.

REPORT OF CASE

A girl aged 6 years was admitted to a hospital elsewhere on June 24, 1940 for treatment of diabetes which had begun to cause the cardinal symptoms about three weeks before. She quickly improved under treatment with diet and insulin, and on July 4 the parents were informed that she would be ready for discharge the following day. She was then receiving daily 25 units of protamine zinc insulin before breakfast.

When the parents went to the hospital to take the child home they found that she was unconscious and had been having a series of convulsions. A letter from the attending physician stated that a severe insulin reaction had developed with twitching and convulsions but that she aroused enough to take some corn syrup and orange juice. Blood sugar at that time, 9:30 a. m., was 52 mg. per hundred cubic centimeters; at 5:30 p. m. it was 64 mg.; she was given 30 cc. of 50 per cent dextrose, because she still had convulsions with twitching of the right arm and right side of the face. The temperature, which had been normal in the morning, went to 102, the pulse to 110 a minute and the respiratory rate was 8. She appeared to have some rigidity of the neck. The spinal fluid was normal but under considerable pressure. She remained in a stupor for three days. When she aroused, she had hemiplegia of the right side and aphasia.

The child showed gradual improvement but when she was discharged from the hospital in the middle of July she still had weakness affecting the right arm, and she walked with a limp. She gained strength slowly but did not regain the full use of her limbs. She showed complete aphasia until July 19; then she became able to say single words. Convulsive seizures and spasms affecting the right arm and leg and the right side of the face occurred at intervals, varying in degree and intensity. They became more frequent in the autumn, and during the first part of November they occurred daily.

The diabetes was difficult to control. Regular insulin had been substituted for protamine zinc insulin after the accident. As a rule, from 5 to 10 units of insulin was given before each meal. Some of the tests of the urine were sugar free, but it seemed impossible to control the glycosuria continuously. Convulsive seizures occurred on some occasions soon after insulin had been administered. The parents came to think that the seizures were caused by the insulin, and when the attacks came so frequently they stopped the injections in desperation on November 10.

The child rapidly became seriously ill with the usual symptoms of acidosis. She was rushed to the hospital in Boston and on November 12 arrived in severe diabetic coma. The blood sugar was 820 mg. per hundred cubic centimeters; the carbon dioxide combining power of the plasma was approximately 1. Treatment with 230 units of insulin in divided doses supplemented by the usual measures brought about gratifying recovery, and the child was fully conscious the following morning. The diabetes was finally brought under control with 15 units of protamine zinc insulin before breakfast and 5 units of regular insulin before supper and supper.

C., Jr.: Hyperinsulinism and Cerebral Changes; *Report of Case Due to Islet Cell Adenoma of the Pancreas*, Arch. Int. Med. 61: 579-599 (April) 1938. Layne, J. A. and Baker, A. B.: Hypoglycemic Cerebral Damage in Diabetic Patients, Minnesota Med. 22: 771-776 (Nov.) 1939. Klein, F., and Ligerink, J. A.: Insulin and Cerebral Damage, Arch. Int. Med. 65: 1085-1096 (June) 1940.

Examination after the coma subsided showed slight weakness and awkwardness in the right arm and slight dragging of the right leg when walking. She continued to show the aphasia. Spasms affecting the right cheek occurred on two occasions. Treatment with phenobarbital $\frac{1}{4}$ grain (0.016 Gm.) three times a day was prescribed to control these attacks. While in the hospital she gained more control of her limbs and further improvement occurred gradually after dismissal from the hospital on November 20. She also made a little improvement in her ability to speak. At the last report, received in October 1941, she was still handicapped by aphasia. Slight epileptic seizures occurred at intervals.

An electroencephalogram made by Dr. Knox H. Finley showed abnormal brain waves, reproduced in the accompanying illustration. There was diffuse abnormal activity which was most pronounced from the left hemisphere, without, however, being limited to any particular part.

Electroencephalogram. Six simultaneous recordings (six channel electrocardiographic apparatus) from the occipital, temporal and frontal leads to occipital areas of each hemisphere. From each three pairs of homologous leads it will be noted that the slow 3 to 4 per second high voltage activity is more pronounced from the left than from the right in each instance, demonstrating a greater degree of disturbance of the cerebral electrical activity from the left hemisphere than from the right. Some runs of normal 9 per second cycles are observed from the right occipital and right frontal to the occipital leads. Not one is observed from leads over the left hemisphere.

COMMENT

One can assume that the occurrence of coma and convulsions under the conditions described must have been due to an insulin reaction, and this opinion was confirmed by the blood sugar reports furnished by the attending physician. The subsequent ill effects can be attributed to organic changes in the brain from the prolonged hypoglycemia. There can be little doubt that this patient has had damage similar to that described in cases in which hypoglycemia has been fatal. The prognosis must be considered serious, but the recovery of function of the arm and leg, together with improvement in speech, is encouraging. Yet the persistence of some degree of mental dulness, partial aphasia and epileptic symptoms for fifteen months limits the hope of complete recovery of cerebral function. The experience with a case such as this indicates the need for caution in the prevention and treatment of severe hypoglycemic reactions when even moderate doses of insulin are employed.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

TREATMENT OF YELLOW FEVER

FRED L. SOPER, M.D.

RIO DE JANEIRO

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.

In the treatment of yellow fever there is only one rule: do not kill the patient.—*Miguel Couto.*

The therapy of yellow fever can be given in a single line: the disease cures itself or kills in spite of any and every treatment.—*Sinval Lins.*

These aphorisms summarize the experience of the Brazilian medical profession in Rio de Janeiro from 1849 to 1908 and in 1928-1929; Couto, for many years the revered dean of the national profession, practiced in Brazil's capital during the last two decades of yellow fever endemicity and was still active during the 1928-1929 epidemic, and Lins was in charge of the hundreds of patients isolated in the São Sebastião Hospital during this epidemic. Observations on experimental infections in the rhesus monkey since 1927 have confirmed this extreme therapeutic pessimism. A consideration of the etiology, pathology and symptomatology of yellow fever aids in understanding the difficulties of attempting specific therapy. Fortunately the situation with respect to prophylaxis is much more favorable.

DEFINITION

Yellow fever is a short, self-limited infection caused by a specific virus, followed by an intoxication due in large part to the destruction of tissue cells, especially the parenchymal cells of the liver.

ETIOLOGY

Man may acquire yellow fever in nature as a link in the man-Aedes aegypti-man chain of the urban disease or as an offshoot of the vertebrate-invertebrate-vertebrate jungle cycle of infection. Clinically, pathologically and immunologically the disease is identical whatever the source of infection, domiciliary or forest.

The specific virus of yellow fever is one of the smaller pathogenic filtrable viruses. Active yellow fever virus is highly antigenic in man and monkeys and is very susceptible to the antibodies produced. Although differences in behavior in test animals can be demonstrated for viruses just isolated from patients with yellow fever and for others modified in various ways in the laboratory, these differences are not sufficient to permit immunologic differentiation.

The term "pantropic" is applied to yellow fever virus as isolated from patients with this disease since it possesses both viscerotropism and neurotropism. Pantropic virus produces visceral yellow fever in rhesus monkeys, whether inoculated subcutaneously or intracerebrally, but produces, following intracerebral inoculation, encephalitis in the white mouse which is not susceptible to visceral yellow fever. The viscerotropism of the pantropic virus can be readily reduced by repeated brain to brain transfer in the mouse, but such repeated transfer augments the neurotropism, as shown by the short-

ened incubation period between inoculation and the onset of encephalitis. The neurotropic virus thus obtained no longer produces visceral yellow fever in rhesus monkeys, but intracerebral inoculation is followed by fatal encephalitis. The simultaneous reduction of both viscerotropism and neurotropism has been accomplished (vaccine virus 17D) but is much more difficult and uncertain. The reduction in viscerotropism is apparently much greater than that of neurotropism; the modified virus kills the white mouse with encephalitis, but only after a prolonged period of incubation, and produces encephalitic symptoms in a certain percentage of rhesus monkeys.

The virus of yellow fever has been shown to exist in the blood stream, in quantities sufficient to infect mosquitoes, only from the first to the end of the third day, although the more sensitive mouse inoculation test has shown some virus in human cases as early as four hours before and as late as the beginning of the fifth day after onset. The disappearance of virus from the blood stream is correlated with the development of antibody which may be present in amounts sufficient to protect white mice by the end of the fourth day. Virus and antibody have been shown to coexist on the fourth day, and positive results from the mouse protection test have been reported for cases which later progressed to a fatal termination. The high concentration of active virus in the blood stream corresponds to the initial period with symptoms of infection, whereas virus is either absent or present in minimal quantities during the period of intoxication. The inoculation of even large amounts of inactivated virus is not followed by the production of antibody nor by signs of intoxication. The symptoms of the intoxication phase of yellow fever cannot, then, be attributed to inactivated virus.

MORBID ANATOMY

Internally, the gross autopsy generally reveals jaundice, hemorrhage, a pale yellow, fatty liver, a pale, flabby heart and tense, swollen kidneys. Greater or lesser evidence of hemorrhage may be found in the stomach, intestine, gallbladder, epicardium and pericardium, meninges, uterus, pleura, lungs and bladder.

The most important microscopic lesions of yellow fever consist of degenerative changes, fatty degeneration and necrosis of the parenchyma, with almost no inflammatory reaction. Many organs and tissues are affected by these changes, but those of the liver, kidney and heart are most important.

Liver.—The extent of injury to the liver revealed by microscopic examination is surprising in the face of its relatively normal gross appearance. The lesion is complex, involving the parenchymatous cells in necrobiosis, necrosis and fatty degeneration. The degree of necrotic change may range from 5 to 95 per cent of the parenchymal cells. In extreme cases only a few cells, recognizable as hepatic parenchyma, may be found close to the portal sheath at the periphery of the lobule and a few others forming a rim of scattered cells about the central vein.

Fatty changes are always found in the liver of patients with yellow fever, but the extent of involvement varies widely from patient to patient. There is no evidence of damage to the stroma.

Kidney.—The reaction of the kidney to yellow fever is like that of the liver: degenerative, not inflammatory. The lesion varies greatly from cloudy swelling to severe

fatty degeneration and necrosis and is not necessarily correlated with the alterations of the renal function observed. The convoluted tubules of the cortex are especially subject to damage, but the medullary tubes may also suffer. The glomeruli may show congestion and some exfoliation of surface epithelium.

Heart.—Well defined degenerative noninflammatory changes may be found in all parts of the myocardium, including the sinuatrial node, the auricle, the auriculo-ventricular bundle and the ventricle. Granular and fatty degenerations of the muscular fibers are constantly found, hyaline and vacuolar degenerations less frequently. The degenerative lesions of the myocardium are sufficient to explain the functional disturbances encountered in yellow fever, such as bradycardia, lowered arterial pressure, severe asthenia, venous stasis and electrocardiographic irregularities.

The lesions are not equally severe in all organs of the same patient; when the liver is badly damaged the heart may escape lightly, or vice versa, while in other instances the kidneys seem to bear the brunt of the attack. There is, however, in all cases resulting in death an appreciable necrosis of liver tissue, and this is the most constant as well as the most characteristic lesion of yellow fever.

BLOOD CHEMISTRY AND METABOLISM OF YELLOW FEVER

Studies on the rhesus monkey infected with yellow fever show that the chemical components of the blood serum and the metabolic functions of this animal suffer little change during the first stage but shortly before death undergo important modifications of a character often found correlated with extensive destruction of liver tissue.

Early changes, which may appear some days before death in rhesus monkeys, include:

1. Increased bilirubin content of the blood.
2. Diminished rate of excretion of bromsulphalein dye.
3. Lowered fibrinogen content of blood, associated with increased clotting time.

Later changes, generally apparent only on the last day before death, include:

4. Progressive hypoglycemia, at first slight, preceding alteration in nitrogenous elements and becoming severe in later stages.
5. High concentration of nonprotein nitrogen in the blood.
6. Absolute increase in urea concentration, proportionately less than the increase of nonprotein nitrogen.
7. Increase of amino acid nitrogen, proportionately greater than the increase of nonprotein nitrogen.
8. Increase of rest nitrogen.

Creatinine increases but little, and that only immediately before death, probably as the result of a terminal anuria, while uric acid does not increase at all and the percentage of the total nonprotein nitrogen of these two constituents is greatly reduced. Attention should be called to the occurrence of extreme hypoglycemia without hyperuricemia. Hypoglycemia is a common finding in human infections of yellow fever.

Only if yellow fever has produced obvious symptoms of intoxication do the concentrations of the nitrogenous constituents of the blood become appreciably altered. The most significant change is that in the amino acid nitrogen, which shows strikingly large gains both in absolute amount and in relation to total nitrogen. The changes noted indicate a loss of ability to deaminate amino acids and to form urea, a deficiency of uric acid

production and an impairment of hepatic glycogen formation, all of which are found following hepatectomy. It is difficult to escape the conclusion that they are dependent on a destruction of the liver parenchyma. Although the kidneys are functionally damaged, the retention by the rhesus kidney of the ability to produce urine in normal amounts and of normal concentration throughout the preintoxication stage of yellow fever indicates that this damage is not the chief factor in the production of the most characteristic disturbances of the disease. No definite evidence of serious impairment of kidney function was observed except terminal anuria.

A significant increase of guanidine in the blood has been found in monkeys, and a similar finding has been reported in a human case. A similar increase of guanidine in the blood has been found in other diseases and intoxications in which extensive damage to the liver occurs, such as carbon tetrachloride, phosphorus, arsenamine, chromium and chloroform poisoning, acute yellow atrophy, Laënnec's cirrhosis of the liver and eclampsia. Guanidine poisoning in dogs produces bloody vomit, hypoglycemia, depression, prostration and death, with autopsy showing hemorrhagic areas at the pyloric end of the stomach and in the duodenum. The similarity of this picture to that of yellow fever is pronounced.

CLINICAL PICTURE

The clinical picture of yellow fever may vary as much as do those of measles, smallpox, poliomyelitis and other virus diseases. Yellow fever may be seen as:

1. Inapparent infection recognized only through proof of acquired immunity.
2. Abortive infection with vague initial symptoms suggestive of mild influenza, lasting only some hours or possibly one day, often recognized only by slowing of the pulse during convalescence.
3. Incomplete attacks with severe onset, high fever, headache, body pains, dizziness and temperature and pulse curves typical of yellow fever but without hemorrhage, jaundice and anuria. Albuminuria and cylindruria may appear suddenly and increase rapidly on the third, fourth or even fifth day in the absence of other severe symptoms.
4. Complete attacks, classic yellow fever. In these cases, following a typical severe onset with symptoms of severe infection, there occur during the second stage albuminuria, hemorrhage and jaundice. The classic attack may be mild if the hemorrhage does not become excessive and the kidneys do not continue to secrete. Severe oliguria and anuria are found only in cases presenting hemorrhage and jaundice.

The clinician notes in the early phase of classic yellow fever the usual signs and symptoms of acute infection but finds nothing to prepare him for the overwhelming intoxication which supervenes as the infection itself declines. The classic clinical picture of yellow fever is one of intoxication rather than of infection and consists of a symptom complex associated with the loss of hepatic and renal function, which is common to a number of diseases and intoxications producing destruction of liver parenchyma. This complex is not pathognomonic of yellow fever; it is the sequence of symptoms, rather, that is the most characteristic feature of the disease.

Period of Infection.—The onset of yellow fever is dramatic in the rapidity with which, within a period of a few hours, an apparently well person is transformed into a very sick patient. The symptoms—headache, backache, pain in the legs, malaise, nausea and vomiting—are out of all proportion to the physical examination.

In many cases the infection of yellow fever is explosive, the pulse and temperature reach their fastigia on the first day, after which there is a tendency for both to decline, the pulse falling sooner, more rapidly and more constantly than does the temperature. This behavior of the pulse and temperature is probably the most constant and characteristic individual finding in yellow fever. Although the temperature often shows a secondary rise during the phase of intoxication, the pulse seldom does, in uncomplicated cases, except in extremis. Bradycardia is common after the third day.

The general picture presented by the patient during the period of infection is one of active congestion accompanied by severe prostration. Nausea and vomiting, associated with this period, are not necessarily indicative of a serious prognosis, and the early appearance of a relatively heavy albuminuria is of diagnostic rather than of prognostic importance.

Generally at the end of the first forty-eight to seventy-two hours the congestion declines, the temperature reaches normal or even subnormal levels and the patient enters a period of relative tranquillity which marks the end of the period of infection.

Period of Intoxication.—About the end of the third day, but sometimes as late as the fifth, the entire clinical picture changes. The active congestion of the previous period is replaced by a venous congestion, accompanied by low arterial tension; nausea and vomiting, which may have been present during the period of infection, are now more severe and are of grave import. Overwhelming intoxication becomes apparent with the appearance of the formidable triad albuminuria, hemorrhage and jaundice. In fulminant attacks symptoms of intoxication are precocious and merge with those of the phase of the infection.

Jaundice.—The jaundice of yellow fever may be so slight as to be missed by the inexperienced, and is rarely or never intense in early cases. Subicterus is the most common finding and may be noted in the conjunctivas as early as the end of the second day, but severe, visible cutaneous icterus appears late and is not found in the fulminant type of the disease, in which symptoms of intoxication appear before those of infection have abated.

Hemorrhage.—The amount of hemorrhage noted in cases of yellow fever varies greatly, but some tendency to hemorrhage is to be found in the majority of clinically diagnosable cases. Although slight hemorrhage may, and often does, occur during the initial stage of active congestion, the dangerous, typical hemorrhage of yellow fever is that of the second phase. Serious hemorrhage generally develops somewhat later than does albuminuria, although in fulminant attacks second phase hemorrhage may begin as early as the end of the second day. Hemorrhage may be so severe as practically to exsanguinate the patient and is undoubtedly often the immediate cause of death.

Albuminuria.—The onset of albuminuria is rapid, as if some sudden, violent intoxication involving renal function had occurred rather early in the course of the infection. From a normal urine, or one showing only the traces of albumin usually found in cases of febrile involvement, a sudden jump to 3 or 4 Gm. of albumin per liter, with hyaline and granular casts, may occur in eight or ten hours, as early as the end of the second day or as late as the fourth or even the fifth day of illness. Albuminuria is almost a constant finding in cases of yellow fever, and even cases of mild involvement will usually show some albumin if carefully studied.

throughout. Practically all cases of severe yellow fever show a much heavier albuminuria than would be expected in severe fevers due to other causes. Heavy albuminuria may be found in cases showing no other severe symptoms and is not in and of itself of serious prognosis.

Anuria, the most dreaded symptom of yellow fever, may occur unexpectedly in cases presenting an otherwise favorable prognosis. Anuria apparently depends on an entirely different mechanism from that producing precocious albuminuria. The former is never found without other signs of destruction of the liver, whereas the latter may be heavy in cases of mild disease without such signs. Anuria follows and seems to depend on hepatic involvement; albuminuria may precede and even be independent of other signs of hepatic intoxication. It is probably safe to conclude that albuminuria may occur either as a result of direct involvement of renal function during the phase of infection or later because of intoxication secondary to destruction of hepatic parenchyma but that anuria is produced only by this secondary intoxication.

TREATMENT

Virus diseases are, in general, noteworthy for their variability in severity. Yellow fever is a prominent example of such variability and is also a disease of uncertain prognosis. Only with a knowledge of these characteristics is it possible to understand the past acceptance and popularity of many forms of treatment for yellow fever, since abandoned. Once yellow fever has declared itself, there are no known specific serologic or chemical therapeutic agents of value.

Serum Treatment.—The demonstration of successful immune serum therapy in other infectious diseases led to the hope that it might be useful in yellow fever, which constantly produces a high grade and permanent immunity in man. Although the inoculation of small amounts of immune serum just before, together with or within a few hours after the inoculation of yellow fever virus in rhesus monkeys has been found efficient in preventing the multiplication of virus and the development of infection, the use of relatively large amounts of such serum soon after onset of symptoms in either man or monkey has not appreciably altered the course of the disease. A possible explanation of these observations is to be found in the behavior of the virus and immune serum in tissue culture. Simultaneous inoculation of immune serum with the virus in tissue culture prevents growth of the virus, whereas addition of immune serum to tissue culture in which the virus is already developing results in sterilizing the liquid part of the culture but fails to inactivate or prevent the development of the virus already within the cellular elements of the culture.

Apparently the onset of symptoms in yellow fever occurs only after the virus has been widely distributed and safely entrenched within the cells throughout the body.

Prophylaxis.—Immune serum was extensively used for the protection of laboratory workers exposed to yellow fever virus previous to the development of vaccination with modified strains. Experience shows that such passive immunization is fleeting and uncertain and should not be relied on for more than a few days following inoculation.

Active modified strains of yellow fever virus have been used for immunization since 1931. The first of these used, having a reduced viscerotropism but

increased neurotropism, was considered unsafe by American workers unless combined with immune serum. This requirement greatly limited its application. In the Americas, in England and in the British colonies in Africa, vaccination has since 1937 depended on the use of another strain, known as 17 D, which has not only lost in great part its viscerotropic affinity for liver and kidney tissue but also, in contrast with the strain previously used, shows a greatly reduced neurotropism.

Virus 17 D grows readily in chick embryo, and the infected embryo itself is used in the preparation of the vaccine. Only one inoculation is given. Successful vaccination depends on delivering living virus under the skin of the person being vaccinated. Inactivated virus is not antigenic, and every precaution should be taken to protect vaccine virus against moisture, heat, sunlight and other harmful agents.

Reactions to virus 17 D are generally unnoted or consist only of slight headache and malaise for some hours five to eight days after inoculation.

In most cases in which tests have been made the active immunity produced by virus 17 D has persisted unaltered during the four year period since the field use of this vaccine began. Only after the lapse of a longer period can conclusions regarding its duration be drawn.

Symptomatic Treatment.—Although there is no specific treatment of yellow fever, there are certain clear indications for careful handling of all cases, even apparently those of mild involvement.

To meet the involvement of the circulatory system which occurs early, is often severe and may persist far into convalescence, the patient should have from the beginning absolute bed rest in a recumbent position. The patient should not be moved from the place of attack, especially after the first day. The reassumption of activity during convalescence should be very gradual. Careful nursing is essential.

The gastrointestinal tract should be relieved of its routine responsibilities. An initial saline purge may be given on the first day, followed by daily enemas. Abstinence from food, except fruit juices to combat hypoglycemia, should be absolute during the phase of infection and, until after the temperature has returned to normal, in the phase of intoxication. Water, Vichy water or water alkalinized with sodium bicarbonate, and citrus fruit juices may be given frequently in small amounts. If vomiting prevents taking liquids by mouth, recourse may be had to intravenous dextrose, physiologic solution of sodium chloride by hypodermoclysis and tap water by rectum. For direct relief of vomiting, cracked ice and cocaine hydrochloride 0.015 Gm. ($\frac{1}{4}$ grain) U. S. P. may be given by mouth and codeine sulfate 0.03 Gm. ($\frac{1}{2}$ grain) U. S. P. by hypodermic injection. Feeding should be resumed slowly, beginning with chicken broth, buttermilk, rice water, crumbled egg yolk and easily digestible liquids with added lactose.

A high temperature may be relieved by an ice cap to the head and by tepid sponge baths. Depressant antipyretic drugs should not be used.¹

The results of chemical analysis of the blood would seem to indicate the use of dextrose to combat hypoglycemia and of calcium salts to neutralize the guanidine-like toxins common in conditions causing

1. Quinine should be administered to patients with fever in regions in which yellow fever may be present only after confirmation of the diagnosis of malaria by examination of the blood film.

destruction of liver parenchyma. The use of calcium lactate and dextrose, so successful in some other intoxications, has not been followed by recovery of monkeys showing signs of intoxication, nor have striking results in man been demonstrated.

Further studies of the effect of these substances would seem to be indicated. The rhesus monkey may not be suitable for such studies, since it is more susceptible to the substances producing intoxication in yellow fever than is man. It is to be hoped that few opportunities will occur for future observation of therapeutic measures in yellow fever in man. The possibility of completely eradicating *Aedes (Stegomyia) aegypti* from towns, cities and even entire states makes future urban outbreaks unnecessary, and vaccination is available for the protection of populations exposed to jungle yellow fever. The proper application of these prophylactic measures should prevent the occurrence of outbreaks to supply the necessary cases for observation.

To close these remarks on the treatment of yellow fever on the same pessimistic note on which they opened, it is fitting to quote from Lins again:

. . . alkalis and acids, glucose and insulin, serum and blood of convalescent cases, transfusion of normal blood,, anti-yellow fever serum, specific vaccine therapy, bleeding, injections of lugol [compound solution of iodine], of permanganate, of hyposulfite of sodium, of calcium, of chlorides, colloids, bismuth preparations, hemostatics of all kinds, and finally antitryptic serum in large doses, all were tried in vain against this terrible disease. Never did I observe beneficial effects from any of these remedies; in not a single case did I have the satisfaction of believing that my treatment had improved the condition of this patient or that one, much less that it had been responsible for saving the life of this or that individual. The moribund whom I saw resuscitated were saved by a miracle and owe nothing to me; likewise, I owe nothing to the athletic young men I saw die except the lingering remorse of having done nothing to save them. . . . I tried innumerable times; but, accomplishing nothing, concluded at last that it was better to fold my arms rather than to contribute to the precipitation of the fatal outcome.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT AND REPORT. AUSTIN E. SMITH, M.D., Acting Secretary.

PRONUNCIATION OF THE WORDS AMIDE, SULFANILAMIDE AND SULFATHIAZOLE

The Council's Committee on Nomenclature has given consideration to the pronunciation of the words amide, sulfanilamide and sulfathiazole.

In harmony with the article "The Pronunciation of Chemical Words—A Report of the Nomenclature, Spelling and Pronunciation Committee of the American Chemical Society" (*Indust. & Engin. Chem., News Ed.*, May 20, 1934, p. 202) the committee recommended that the word amide be pronounced with a long "i" (amide), this being preferable both because of the final e and the analogy with chloride and iodide. For the same reason the committee held that the preferred pronunciation of sulfanilamide should be sulfanilamide with the major accent on the antepenultimate syllable, *il'*.

In agreement with the principle that English accentuation is recessive, it is believed that the preferred accent would be on the syllable *thi* in sulfathiazole.

The Council adopted the foregoing pronunciations.

NASAL INHALANT PREPARATIONS CONTAINING PETROLATUM OMITTED FROM N. N. R.

For several years dosage forms of several vasoconstrictor and other drugs, marketed as inhalants in oily or ointment vehicles consisting wholly or in part of petrolatum (principally liquid petrolatum), have been included in New and Nonofficial Remedies. The previously accepted products of this type contained one of the following in amounts of 1 per cent or less: amphetamine (benzedrine), ephedrine, epinephrine (adrenalin, suprarenalin), neosynephrin hydrochloride and chlorobutanol (chloretone). The vasoconstrictor preparations were recognized for intranasal application to induce shrinkage of the mucous membrane for the relief of nasal congestion accompanying rhinitis (infectious or catarrhal and vasomotor or allergic) and sinusitis.

In a recent report by Cannon¹ published under the auspices of the Council, evidence was advanced to indicate that the promiscuous use of oily nose drops, particularly those containing liquid petrolatum, was dangerous from the standpoint of lipid pneumonia and that the therapeutic rationale of oily intranasal medication deserves reexamination because of evidence to indicate that oil interferes with the normal function of the ciliated epithelium of the upper respiratory tract. The Council has accordingly recently reconsidered the status of previously accepted oily inhalant preparations with the view to determining which types of such products justified continued inclusion in N. N. R.

In its study of oily inhalants the Council has sought the advice of several leading rhinologists. It was the consensus of these authorities that the evidence for the danger of lipid pneumonia from the repeated use of inhalants containing petrolatum warrants the omission of such preparations from New and Nonofficial Remedies, that all oily inhalants are capable of interfering with ciliary action and that isotonic aqueous vehicles are preferable from this point of view. Opinions were not conclusive with regard to the danger of lipid pneumonia following the use of inhalants containing oils other than petrolatum. In view of this and the possibility that the more prolonged contact of drugs with the nasal mucous membrane afforded by viscous vehicles might in some cases outweigh the detrimental influence of oils on ciliary activity, the Council decided that it was advisable to take action to omit from New and Nonofficial Remedies only petrolatum-containing inhalants. It was emphasized that petrolatum-containing preparations have been indisputably implicated in the production of lipid pneumonia, whereas the evidence against inhalants having vehicles containing vegetable oils (either in liquid, ointment or jelly form) as causes of lung irritation remains to be established by further investigation. It was pointed out however that, while there is no evidence that oils produce permanent damage to the nasal mucous membrane, the interference with ciliary function by viscous substances makes it generally preferable to employ local vasoconstrictors in aqueous vehicles which have been rendered isotonic. Meanwhile the Council will retain in N. N. R. only those oily inhalants which do not contain petrolatum, pending the development of more positive evidence concerning the irritative properties of other types of oils. The need for further study of other oils from the standpoint of lipid pneumonia was indicated in a previous report of the Council.²

The Council voted to omit all brands of inhalant nasal preparations containing petrolatum from New and Nonofficial Remedies because of the danger of lipid pneumonia from the repeated intranasal use of such products and the fact that other, safer vehicles for inhalant preparations are available.

Committee on American Health Resorts

THE AMERICAN MEDICAL ASSOCIATION COMMITTEE ON AMERICAN HEALTH RESORTS¹ HAS AUTHORIZED THE PUBLICATION OF THE FOLLOWING RULES FOR THE LISTING OF AMERICAN HEALTH RESORTS. THESE RULES HAVE BEEN ADOPTED BY THE COMMITTEE AND APPROVED BY THE BOARD OF TRUSTEES OF THE AMERICAN MEDICAL ASSOCIATION. THE EXPLANATORY MATTER ACCOMPANYING THE RULES HAS ALSO BEEN APPROVED BY THE COMMITTEE.

W. W. BAUER, M.D.

Recognizing the value of those phases of medical treatment included under the general classification of health resort or spa treatment such as climate, thermal and mineral waters, sea water and peloids (muds), the House of Delegates of the American Medical Association in 1938 authorized the appointment of a Committee on American Health Resorts. This committee was accordingly appointed by the Trustees.

The committee first prepared a questionnaire which could be sent to known health resorts asking for information as to their natural therapeutic resources, domiciliary and recreational facilities and, more important, the medical facilities available and the medical supervision of the use of therapeutic facilities available.

A list of health resorts was then compiled from various sources including books, government publications, the records of the American Congress on Physical Therapy, tourist guides and miscellaneous sources.

Through an extensive survey by questionnaire and correspondence a comprehensive list was developed of health resorts in the United States including those with and without medical facilities.

The committee next proceeded to establish and define certain minimum fundamental standards which would assure the safe and successful use of natural therapeutic resources according to established scientific procedure. These standards have been expressed in the rules published herewith. These rules are subject to modification as experience indicates.

The committee now plans to offer an opportunity to American health resorts to apply for a listing which the committee proposes to compile. This listing will include health resorts which comply with the rules of the committee. Application blanks will be furnished on request addressed to the Committee on American Health Resorts, American Medical Association, 535 North Dearborn Street, Chicago.

On receipt of an application² properly filled out the committee will, with all possible promptness, cause inspection to be made of the applicant's premises and will make such other investigations as the committee may deem advisable. A report will be compiled, submitted to the applicant and published. If the applicant is found to comply with all the rules of the committee, the name of the health resort will be included in the committee's list during such time as compliance with the rules of the committee continues.

When any modifications of the rules are deemed necessary, those resorts already listed under rules as previously adopted will be notified promptly and will be given reasonable opportunity to comply with the modified ruling or voluntarily to withdraw from the listing.

RULES

Object of Rules.—The following rules with such amendments as may be added from time to time have been adopted by the

1. Following are the members of the committee: Walter S. McClellan, M.D., acting chairman, Saratoga Springs, N. Y.; William P. Holbrook, M.D., Tucson, Ariz.; Nilius B. Jarman, M.D., Hot Springs, Va.; Frank H. Krusen, M.D., Rochester, Minn.; Euclid M. Smith, M.D., Hot Springs, Ark.

Committee on American Health Resorts of the American Medical Association with the primary object of identifying for the medical profession and the public those health resorts which are shown by investigation of their location, climate, personnel and management to merit recognition by the medical profession.

Definition.—A health resort is defined as "an institution which gives major attention to the use of the special climatic and other natural therapeutic resources including mineral waters, peloids, etc., with which it is endowed by reason of its location." While the use of the natural resources is the prime object or purpose of the institution, other remedies may be applied as an adjunct.

List.—American Health Resorts which are found by the committee to conform to the letter and spirit of the following rules will, on application approved by the committee, be placed on a list to be published by the committee:

RULE 1.—Application.—To be considered for inclusion in the committee's list, formal application must be made to the committee according to the following formula:

(a) Formal application for consideration written on stationery of the applying health resort, addressed to the Secretary of the Committee on American Health Resorts, American Medical Association, 535 North Dearborn Street, Chicago.

(b) This application should be accompanied by complete information on: (1) ownership, (2) personnel, (3) equipment, (4) method of operation, (5) method of promotion.

(c) Eight copies each of all recent advertising, descriptive booklets, pamphlets, circulars, promotional form letters and any other promotional matter pertaining to the health value of the resort should be submitted.

(d) All correspondence with the secretary should be in duplicate.

RULE 2.—Claims and Advertising.—The claims made for a resort must be acceptable to the committee, and all advertising material must be presented with applications. A resort will not be listed or retained if the management makes unwarranted, exaggerated or misleading statements in any of its advertising.

RULE 3.—Medical Supervision.—Medical supervision must meet with the approval of the committee and must be of such character as to place proper safeguards about the patient to protect him from mistreatment or dangerous treatment. Institutions which permit attendants or technicians to alter or supplement a physician's prescription or to prescribe treatment without restrictions or medical supervision will not be listed. An institution applying for listing will be scrutinized most carefully as to the character of the safeguards placed about the patient by way of medical supervision and the efficiency and good faith with which the rules governing these needs are enforced.

RULE 4.—Inspection.—An institution which makes application cannot be given formal consideration until it has been inspected by an inspector designated for the purpose by the committee.

RULE 5.—Removal from List.—If in the opinion of the committee a listed institution fails to live up to the letter and spirit of these rules or engages in practices contrary to established scientific procedure, the committee may remove the institution from the list.

RULE 6.—Committee Decision Final.—In making application for inclusion in the committee's list, the applicant agrees that final decision as to listing, nonlisting or subsequent removal shall rest with the committee.

2. Application blanks will be furnished free on request addressed to the Committee on American Health Resorts, American Medical Association, 535 North Dearborn Street, Chicago. The request should be on the letterhead of the institution.

SATURDAY, JANUARY 31, 1942

NEWER KNOWLEDGE OF DIPHTHERIA GRAVIS

Studies of production of toxin by malignant strains of *Corynebacterium diphtheriae* recently reported by O'Meara¹ of Trinity College, Dublin, and by Mueller² of Harvard University have led to a new and clinically plausible theory of the etiology of diphtheria gravis. The optimism that prevailed during the first three decades of the twentieth century with regard to the successful therapeutic control of diphtheria yielded to pessimism and perplexity with the appearance in 1927 of numerous cases of malignant diphtheria in central Europe. Such cases were wholly refractory to routine methods of serum therapy. In certain Berlin hospitals, for example, the diphtheria mortality rose from the previous statistical level of 5 per cent to approximately 30 per cent. Similar high mortalities were afterward reported from France, Czechoslovakia, Italy and Rumania, with a later spread of the epidemic to the British Isles.³

The malignant cases of diphtheria were characterized by evidence of hypertoxicity, severe local edema and necrosis with relatively slight membrane formation in the throat, massive cellulitis ("bullneck") and degenerative lesions in the kidneys, heart muscle, adrenals and nervous tissues, with an occasional focal necrosis in the spleen. Twenty times the usual therapeutic dose of diphtheria antitoxin was injected intravenously in a number of instances without curative effects. By the application of routine cultural methods, morphologically and culturally typical diphtheria bacilli were isolated in the malignant cases. Demonstrable differences in toxin production from standard laboratory strains were not apparent. The usual commercial antitoxin protected laboratory animals equally well against the new toxins. Special antisera prepared by immunizing animals against the new toxins were not found superior to the commercial product.

With the introduction of tellurite chocolate agar as a differential culture medium, however, evidence developed that clinicians were dealing with a hitherto unrecognized type of diphtheria bacillus, easily recognized by its colony morphology. For this strain Anderson⁴ then suggested the name *Corynebacterium diphtheriae gravis* with *Corynebacterium diphtheriae mitis* suggested for the classic relatively nonmalignant strain. The American standard toxin producer (Park No. 8) was found to be half way between the mitis and gravis type and was therefore classified as *Corynebacterium diphtheriae intermedius*. Study of 1,300 cases during the 1936 Ukrainian epidemic showed that this classification has clinical significance. The Zinnemanns,⁵ for example, found that 96 per cent of all cultures isolated during life for all fatal cases during this epidemic were of the gravis type. Most of the nonfatal cases were due to mitis infection.

The first definite explanation of the evident hypertoxicity of gravis strains resulted from altering the routine technic of toxin production in vitro. In the routine method the bacilli are grown for relatively long periods in a liquid medium so as to favor oxidation and enzymic destruction of initial toxic products. To imitate the natural method of growth in the throat, O'Meara cultivated gravis strains for a shorter time (forty-eight hours) on Loeffler's blood serum and extracted the massive growths thus obtained in saline solution. The resulting extracts freed from organisms by centrifugation and Berkefeld filtration were found to be almost free from classic diphtheria toxin, rarely containing more than 0.2 minimum lethal dose per cubic centimeter as determined by animal tests. Injected intracutaneously, however, the gravis extracts produced necrotizing and edematous lesions resembling the local reactions to potent staphylococcus or streptococcus toxins. This dermal toxin was not demonstrated in control extracts from mitis or intermedius strains. From such evidence O'Meara concluded that the main or initial product from gravis strains is an endotoxin analogous to the Duran-Reynolds "spreading factor" formed by certain invasive strains of pyogenic cocci.

If this gravis "spreading factor" is mixed with routine diphtheria toxin and injected subcutaneously in the central part of the guinea pig abdomen, the mixture often produces an enormous edematous lesion extending from the neck to the pubis with subsequent massive necrosis, a phenomenon simulating the massive cellulitis of gravis cases. In such injections the time of death is determined by the routine diphtheria toxin in the mixture and is not related to the amount of gravis factor. From such evidence O'Meara concludes that malignant diphtheria is due to the synergic effects of classic diphtheria toxin with gravis endotoxin. Routine anti-

2. Mueller, J. H.: *J. Immunol.* 42: 343-353 (Nov.) 1941.
3. McLeod, J. W.; Orr, J. W., and Woodcock, Hester E. de C.: *J. Path. & Bact.* 45: 99 (Jan.) 1939.

diphtheritic serum plus an effective antiendotoxin would presumably be necessary for effective serum therapy.

A second equally significant characteristic of gravis strains is their resistance to certain local immunity mechanisms in the throat. Locke and Main,⁶ for example, showed that the production of toxin by classic strains of the diphtheria bacillus is inhibited by slight traces of iron salts added to the culture medium. Pappenheimer and Johnson⁷ found that good toxin was obtained only between extremely narrow limits of inorganic iron, the optimum being well below that often present as an unrecognized impurity in culture materials. The best yield was obtained at a concentration of 0.14 microgram of iron per cubic centimeter. Smaller amounts of iron resulted in poor growth and reduced amounts of toxin. Larger amounts, while consistent with excellent growth, allowed progressively less toxin to be formed, 0.5 microgram per cubic centimeter practically stopping toxin production. Mueller,⁸ who confirmed this work, found that Park No. 8 would produce only about 3 minimum lethal doses of toxin per cubic centimeter at an iron concentration of 4 micrograms, 800 minimum lethal doses per cubic centimeter being produced at the optimum iron concentration (0.14 microgram). Analyses of diphtheria membranes suggest that 4 micrograms per cubic centimeter is approximately the iron concentration in the throat. Less than 0.5 per cent of maximum toxin yield is therefore presumably produced by Park No. 8 under the inhibiting influence of the simpler iron compounds (including hematin) of the pharyngeal mucosa.

A parallel study of typical gravis strains isolated from the recent Halifax epidemic showed a similar inhibiting effect. Gravis strains, however, are more resistant to this inhibition, being able to produce nearly 40 per cent of their maximum yield in spite of this pharyngeal inhibition. This is approximately thirteen times the amount of toxin that can be produced by mitis or intermedius strains under similar conditions.

Evidence of a new toxic factor formed by the gravis bacillus and the evidence of gravis resistance to the normal inhibiting mechanism of the throat replaces the pessimism and perplexity of the last decade with a definite working hypothesis, renewing hope of ultimate clinical mastery of malignant diphtheria. Thus far diphtheria gravis has not attained a permanent foothold in the Western Hemisphere, the recent Halifax epidemic⁸ having been successfully combated by vigorous cooperation of civil and military authorities. Perhaps its reintroduction under prospective wartime conditions is inevitable.

LISTING AMERICAN HEALTH RESORTS

The American Medical Association Committee on American Health Resorts was created by action of the Board of Trustees in 1938. Rules are published elsewhere in this issue of *THE JOURNAL* (page 379) according to which the committee proposes to compile a list of American health resorts which voluntarily choose to comply with the rules of the committee and to apply for listing on that basis.

With foreign health resorts unavailable and with the possibility that facilities of health resorts may be called on for the treatment of battle casualties and diseases arising out of military service, such resorts in the United States acquire new significance. In the United States, natural facilities encompassed in the usual conception of health resort or spa therapy, such as climate, mineral waters for bathing, drinking or packs and peloids or muds, are exceedingly profuse. The mineral waters in the United States have in various localities the important characteristics of the principal European spas, including gaseous waters, thermal waters, alkaline waters, laxative waters, sulfur waters and other types. The utilization of these natural resources in the United States has not kept pace with European practices.

The committee has therefore worked along two principal lines: (1) the development of simple yet comprehensive rules which will tend to identify health resorts with adequate facilities and appropriate medical supervision to insure the safety of patients and (2) the development of a series of scientific papers on various phases of health resort therapy. These papers are now in preparation and will appear in *THE JOURNAL* as a series of special articles beginning in the early spring of 1942.

THE CHIROPRACTIC THEORY OF INSURANCE RATING

The principal guide in the rating of insurance companies is known as Best's. This well established system uses alphabetical designations and includes the financial standing of the insurance firm, as well as an evaluation of safety factors based on the surplus, administration and other features essential to the protection of the public.

Recently one George Huff, writing on the stationery of a state chiropractic society and designating himself as Chairman of the Committee on Insurance, wrote to the president of a large insurance corporation. His letter instructed the insurance official to "read the enclosed letter carefully, giving special credence to the importance of this campaign to determine the attitude of every insurance company toward the Chiropractic profession, and advise this office at your earliest con-

6. Locke, Arthur, and Main, E. R.: *J. Infect. Dis.* 48: 419 (May) 1931.

7. Pappenheimer, A. M., Jr., and Johnson, Sylvia J.: *Brit. J. Exper. Path.* 17: 335 (Oct.) 1936.

8. News Item, *Science* (Supplement) 93: 9 (March 28) 1941.

venience, just how soon we may expect your Board of Directors to take the necessary action to qualify your company for the class 'A-1' listing in our new directory." The enclosed letter gave further details concerning the "insurance directory" and stated that some twenty-five thousand copies would be distributed. After mentioning the fact that insurance companies will be classified according to the type of insurance they write—life, health, accident, and so on—it is stated that "For reasons which the Chiropractic profession feels justifiable, all such companies will be further classified under the following ratings:

"Class 'A-1'—will include all companies . . . *who can show proof that they have now appointed Chiropractors as examiners* for their insurance applicants, or their intention to do so. . . .

"Class 'A'—will include all companies *who approve of Chiropractic services for their policy-holders or insureds*, but do not qualify for the 'preferred' class 'A-1' rating, because of failure to specify Chiropractic service in their policies or otherwise fail to qualify for the 'A-1' listing.

"Class 'B'—will contain the names of all companies, associations or societies who fail to report their position concerning this matter to this office, and companies *who are known to have attempted to evade payment of claims on the grounds that their policy-holders did not comply with the terms of their policy by employing the services of a Chiropractor.*" (Italics ours.—Ed.)

The "inducement" for complying with this proposition is presented as follows:

"To estimate the value of the 'preferred' listing to any insurance company in this directory from a dollar and cents angle would, of course, be difficult, because it involves not only the Good Will and fullest cooperation of the 25,000 Chiropractors and their families, but also their millions of patients and friends, which IS something to consider."

The letter proceeded:

"A few of the leaders in the three insurance fields operating in this state were notified of this action two months ago, and most of those contacted have already qualified their companies for the class 'A-1' rating, or are in the process of doing so now" [Sic].

The arrogant effrontery of proposing to classify insurance companies on the basis of their cooperation with chiropractors is not surprising. The pattern was established with the very advent of chiropractors. Certainly insurance companies will be little concerned beyond ordinary annoyance by this promotional material. Equally certain would be the hazard to any company that relied on physical examinations made by chiropractors. In the payment of claims for sickness and accident, the company which settles such claims on the basis of a chiropractor's statement may, at least in most states, be placing itself in the position of not closing the claim. In few states indeed is a chiropractor recognized by law as one qualified to determine the essential facts on which such claim and closure may be based. To place chiropractors in a position to render decisions in such matters would be the height of folly.

BUSINESS WOMEN PROMOTE HEALTH EXAMINATIONS

The National Federation of Business and Professional Women's Clubs, Inc., under the presidency of a physician and with a health advisory committee under the chairmanship of a physician, and with one additional medical member, one dental member and three lay members, has issued a leaflet entitled "Are You Fit for the Job?"¹ This pamphlet explains the health appraisal project of the federation, recommending an annual physical examination for every business and professional woman. The pamphlet analyzes the importance of health and fitness for the job. It sets forth three health ratings—the ideal, which is never wholly attainable; the actual, which is "often far below that which is possible and practicable for the individual," and the attainable, "the health that one might have with the normal appreciation and realization of health that is reasonably available for the individual." The pamphlet reproduces a health appraisal form which is to be offered the examining physician. It includes a philosophy of health and fifteen points in a healthy personality. The pamphlet also supplies instructions for health appraisal projects for local business and professional women's clubs, including a meeting for discussion to be followed by efforts to attain 100 per cent physical examinations by physicians, followed by appropriate corrective measures. Accompanying the pamphlet is a four page letter size folder carrying on its first page an introduction "To the Examining Physician: The patient presenting herself to you for examination is a member of the National Federation of Business and Professional Women's Clubs who wishes to obtain the optimal level of health possible for her. . . . She is presumably a well person actively engaged in business or in a profession. . . . This examination form has been prepared to include not only a record of physical history and physical findings but also the questions which will aid you and the patient in evaluating her design for living which should make for an integrated personality. . . . Your cooperation in obtaining a complete history and giving a careful and complete physical examination will be appreciated." Page 2 contains a form for recording an exceptionally complete health history; page 3 provides for recording a complete physical examination, including routine pelvic examinations recommended for all women but stating that special tests such as blood counts, roentgenograms, basal metabolic rate determinations, blood chemistry and the like are "recommended as indicated, but not included in routine health examination." The entire blank is to be returned to the patient for her information and subsequent guidance. This is a well conceived project which, if carried out locally according to the instructions so well developed by the national body, deserves the widespread cooperation of physicians.

1. National Federation of Business and Professional Women's Clubs, Inc., 1819 Broadway, New York. Single copy, 10 cents.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PHYSICAL REHABILITATION OF REGISTRANTS

According to a statement by Lewis B. Hershey, director of Selective Service, signed January 17, as noted in the *Federal Register*, January 21, the Selective Service regulations are amended by adding thereto a new part reading as follows:

PART 661—PHYSICAL REHABILITATION

REHABILITATION PROCEDURE

- Sec.
661.1 Determination that registrant's defects are to be remedied.
661.2 Notice to registrant to appear for consultation.
661.3 Conference with registrant and selection of physician, dentist or facility.
661.4 Use of government facilities.
661.5 Inquiry for undertaking of services to physician, dentist or facility.
661.6 Order to registrant to have defects remedied.
661.7 Procedure when registrant desires to have his defects remedied at his own expense.

DISPOSITION OF REHABILITATED REGISTRANT AND REGISTRANT WHO REFUSES TO HAVE DEFECTS REMEDIED

- Sec.
661.11 Submission of rehabilitated registrant for further physical examination by the armed forces.
661.12 Procedure when registrant refuses or fails to have his defects remedied.

DESIGNATION AND PAYMENT OF PHYSICIANS, DENTISTS AND FACILITIES

- Sec.
661.21 Designated physicians, dentists, and facilities.
661.22 Schedule of fees for the Selective Service System.
661.23 Procedure for payment of fees.

REHABILITATION PROCEDURE

§ 661.1 *Determination that registrant's defects are to be remedied.* When the Report of Physical Examination and Induction (Form 221) is received by the local board from the examining station of the armed forces with the certification that the registrant is physically and mentally qualified for military service after the satisfactory correction of certain specified remediable defects, and when the specified remediable defects are of the type which the Director of Selective Service has determined shall be remedied, the local board, in accordance with instructions issued and subject to limitations imposed by the Director of Selective Service, and with one or more of its examining physicians or dentists present as advisers, will consider whether it is practicable to remedy such defects of the registrant within a reasonable time and at a reasonable cost. If at this time or at any subsequent time there is not an agreement between the examining physician or dentist and the local board concerning the practicability of correcting such remediable defects of a registrant within a reasonable time and at a reasonable cost, the local board may send the record of the registrant or, if necessary, may send the registrant to the medical advisory board for an opinion from the appropriate member or members of that board and, giving consideration to such opinion but not being bound thereby, shall determine the course to be followed.*

§ 661.2 *Notice to registrant to appear for consultation.* If the local board decides that the remediable defects of any regis-

trant are of a type which the Director of Selective Service has determined should be remedied and that such defects can be remedied within a reasonable time and at a reasonable cost, the local board will issue a Notice to Registrant to Appear for Consultation (Form 225) which will state the hour, date, and place the registrant shall report for conference with the local board.*

§ 661.3 *Conference with registrant and selection of physician, dentist or facility.* (a) When the registrant reports in accordance with a Notice to Registrant to Appear for Consultation (Form 225), at least one member of the local board and one or more of the examining physicians or dentists will confer with him for the purpose of making arrangements for his rehabilitation. If the registrant desires to have his defects remedied at his own expense, see § 661.7.

(b) The registrant will be advised that he has certain remediable defects which may be remedied at government expense. He will also be advised that, if the defects are remedied, he will be returned to the examining station of the armed forces and, if found acceptable to them, will be forwarded for induction in the usual manner. He will be further advised that if he refuses to have his defects remedied, his defects may be waived and in such event he will be subject to induction into the armed forces.

(c) If a registrant agrees to have his defects remedied, he shall name a designated physician, dentist, or facility to undertake his rehabilitation: *Provided*, That the provisions of § 661.4 do not apply: *And provided further*, That, if the registrant desires and requests the services of a physician, dentist or facility that has not been designated, the procedure prescribed in § 661.21 will be followed, and the registrant must name a designated physician, dentist or facility as his second choice to perform the necessary services if the first named physician, dentist or facility is not accepted for designation. The local board, acting for the registrant, must name a designated physician, dentist or facility for the purpose of undertaking to remedy the registrant's defects (1) if the registrant fails or refuses to name a designated physician, dentist or facility, or (2) if the registrant names a physician, dentist or facility not designated but fails or refuses to name as his second choice one already designated and the one not designated named by the registrant fails to qualify for designation. When the local board is required to name a designated physician, dentist or facility as above, it shall do so in the following manner: The record of designated physicians, dentists or facilities furnished the local board by the State Director of Selective Service shall be consulted and the first designated and qualified physician, dentist or facility whose name appears on that record with an office in or near the community in which the registrant lives shall be the first named, the second shall be the second named, the third shall be the third named, and so on consecutively until all such designated and qualified physicians, dentists or facilities have been used, and then the process shall start over again.

(d) The registrant shall execute, in triplicate, a Registrant's Rehabilitation Statement (Form 226). If he refuses to have his defects remedied, he shall state the reason for such refusal.

(e) The signature of the registrant upon the Registrant's Rehabilitation Statement (Form 226) shall be witnessed by a member of the local board and the examining physician or dentist.

* §§ 661.1 to 661.23 inclusive, issued under the authority contained in 54 Stat. 885; 50 U. S. C., Sup., 301-318, inclusive, E. O. No. 8971, 6 F. R. 6419.

(f) If the registrant names a designated physician or dentist who practices, or a designated facility which operates, outside the community in which he lives, and there is a designated physician, dentist or facility in the community in which he lives capable of rehabilitating him, authorization may be granted for the designated physician, dentist or facility so named: *Provided*, That such authorization shall not be made if it results in unnecessary delay in the rehabilitation of such registrant, and *Provided further*, That the expense of transportation to and from the designated physician, dentist or facility shall be borne by the registrant. If there is no designated physician, dentist or facility in the community in which the registrant lives who is qualified and willing to treat the registrant, necessary travel costs to and from the nearest community in which there is a designated physician, dentist or facility qualified and willing to undertake the registrant's rehabilitation will be borne by the Selective Service System, and Government Requests for Transportation (Standard Form No. 1030) and Government Request for Meals or Lodgings for Civilian Registrants (Form 256) may be issued.*

§ 661.4 *Use of Government facilities.* If the Director of Selective Service determines that the facilities of any department, bureau or agency of the Government of the United States should be used in rehabilitating the registrants in any community, such facility shall be used to the extent that the Director of Selective Service may direct.*

§ 661.5 *Inquiry for undertaking of services to physician, dentist or facility.* After the Registrant's Rehabilitation Statement (Form 226) is completed by a registrant who is to have his defects remedied, an Inquiry for Undertaking of Service (Form 227) shall be prepared by the local board, in quadruplicate. It shall be addressed to the designated physician, dentist or facility selected to render the service for a given registrant. It shall set forth the facts relevant to the defects of the registrant and the maximum fees allowable for the correction of such defects. It shall contain an inquiry as to the desire of the physician, dentist or facility to undertake the service indicated. If the physician, dentist or facility offers to perform the services, one copy of the Inquiry for Undertaking of Service (Form 227) will be retained by the physician, dentist or facility addressed, and the original and two remaining copies will be signed and returned to the local board. The local board will forward the original and both copies of Inquiry for Undertaking of Service (Form 227), together with the Armed Forces' Original of the Report of Physical Examination and Induction (Form 221), to the State Director of Selective Service. The State Director of Selective Service shall indicate his approval, disapproval or desired modification on the original and both copies of the Inquiry for Undertaking of Service (Form 227), retain the original and return both copies, together with the Armed Forces' Original of the Report of Physical Examination and Induction (Form 221), to the local board. If the State Director of Selective Service has indicated his approval on the copies of the Inquiry for Undertaking of Service (Form 227), the local board shall forward the approved copy bearing the signature of the State Director of Selective Service to the designated physician, dentist or facility, and such approved copy will constitute authority to render the indicated service. If modifications are made by the State Director of Selective Service, the Inquiry for Undertaking of Service (Form 227), with such modifications, will be resubmitted to the designated physician, dentist or facility concerned for approval.*

§ 661.6 *Order to registrant to have defects remedied.* When the local board has received an approved copy of the Inquiry for Undertaking of Service (Form 227), it shall complete and mail to the registrant an Order to Registrant to Have Defects Remedied (Form 228).*

§ 661.7 *Procedure when registrant desires to have his defects remedied at his own expense.* If a registrant desires to have his defects remedied at his own expense, he may do so without reference to the foregoing procedure; *Provided*, That a program for remedying the defects is presented which is satisfactory to the local board. In such a case the program will be outlined in the Registrant's Rehabilitation Statement (Form 226) and will include arrangements to keep the local board

advised of the registrant's progress. If at any time after making such an arrangement, the registrant fails or refuses to have his defects remedied in the manner agreed upon, the local board may take the steps outlined in § 661.12.*

DISPOSITION OF REHABILITATED REGISTRANT AND REGISTRANT WHO REFUSES TO HAVE DEFECTS REMEDIED

§ 661.11 *Submission of rehabilitated registrant for further physical examination by the armed forces.* (a) The local board will keep informed as to the progress of the registrant while his defects are being remedied. When the registrant's rehabilitation will take more than thirty days the local board will furnish the physician, dentist or facility with sufficient Progress Reports of Rehabilitation (Form 229) so that one of such forms can be completed and returned to the local board each thirty days after the commencement of rehabilitation. A Report of Completion of Rehabilitation (Form 230) shall be filled out and forwarded to the local board by the physician, dentist or facility when the registrant's rehabilitation has been completed. When the physician, dentist or facility which has undertaken to remedy the registrant's defects has forwarded the local board a Report of Completion of Rehabilitation (Form 230), the local board will direct the registrant to appear before the examining physician or dentist of the local board and, in doubtful cases, to appear before the medical advisory board. When the local board is satisfied, from the report of the examining physician or dentist or the medical advisory board, that the remediable defects which were specified in the certificate of the examining station of the armed forces have been remedied, it shall again forward the registrant for physical examination by the armed forces in the manner provided in Part 629; provided that if the effective period for the former physical examination by the armed forces has expired, but not otherwise, it shall prepare a new Report of Physical Examination and Induction (Form 221), the Armed Forces' Original and all copies of which shall be forwarded with the registrant in addition to the Armed Forces' Original of the former Report of Physical Examination and Induction (Form 221). Upon the return from the examining station of the armed forces of the Armed Forces' Original and all copies of the corrected or new Report of Physical Examination and Induction (Form 221), or both, the local board will proceed in the manner provided by § 629.31.

(b) The local board will forward all completed Reports of Completion of Rehabilitation (Form 230) to the State Director of Selective Service for transmittal to the Director of Selective Service.*

§ 661.12 *Procedure when registrant refuses or fails to have his defects remedied.* If the registrant refuses or fails to have his defects remedied, the local board will forward to the State Director of Selective Service the original and one copy of the Registrant's Rehabilitation Statement (Form 226), the Armed Forces' Original of the registrant's Report of Physical Examination and Induction (Form 221) and its recommendation as to the disposition of the matter. Upon receipt thereof, the State Director of Selective Service will either return the file to the local board with further instructions or forward the file, together with his own recommendation, to the Director of Selective Service, or, if so instructed by the Director of Selective Service, to the Corps Area Commander (or representative of the Navy or Marine Corps).*

DESIGNATION AND PAYMENT OF PHYSICIANS, DENTISTS AND FACILITIES

§ 661.21 *Designated physicians, dentists and facilities.* (a) The Director of Selective Service shall prepare and maintain a record of designated physicians, dentists and facilities for the nation. The State Director of Selective Service shall maintain a record of designated physicians, dentists and facilities for his state. He shall furnish each local board with a record of designated physicians, dentists and facilities in or near the community in which each local board is located. If a physician, dentist or facility whose name is not included in the record of designated physicians, dentists or facilities is named by a registrant or makes a request to be designated, the local board shall endeavor to secure a written application from such physician,

dentist or facility. The local board shall forward any application it receives, together with its recommendation thereon, to the State Director of Selective Service.

(b) When the application is received by the State Director of Selective Service, he shall make a thorough investigation as to the applicant's professional and ethical standing in the community. If, after investigation, he is of the opinion that the applicant is qualified, he shall add the name of the applicant to the record of designated physicians, dentists or facilities and so advise the local boards affected. The name and address of each such physician, dentist or facility, together with the application, report of investigation made, and the action taken thereon by the State Director of Selective Service, shall be forwarded to the Director of Selective Service. In the absence of comment by the Director of Selective Service, such physician, dentist or facility shall thereafter be a designated physician, dentist or facility. The Director of Selective Service will notify the State Director of Selective Service in the event of nonconcurrency in the designation of a given physician, dentist or facility.

(c) Nothing herein contained shall prohibit any physician or dentist who is now or may hereafter be appointed an examining physician or dentist or a member of a medical advisory board from applying to the State Director of Selective Service to have his name placed in the record of designated physicians or dentists. Upon the receipt of such an application, the procedure prescribed in *b* above will be followed. If the name of such examining physician or dentist or member of a medical advisory board is placed in such record, he shall receive payment for authorized rehabilitation services in the same manner as any other designated physician or dentist, and the Waiver of Pay or Compensation portion of the Oath of Office and Waiver of Pay or Compensation (Form 21) executed by the examining physician or dentist or member of the medical advisory board shall not operate to prohibit such physician or dentist or member of the medical advisory board from receiving compensation from remedying the defects of a registrant. His services as a designated physician or dentist will be apart from, and in addition to, his present duties as an examining physician or dentist or member of a medical advisory board, which latter duty will remain on an uncompensated basis.

(d) Any designated physician, dentist or facility may be utilized by any local board in the Selective Service System. [See, however, § 661.3 (f).]

(e) A State Director of Selective Service who has reason to believe that a designated physician, dentist or facility does not have the necessary qualifications will suspend such physician, dentist or facility and will report the reason therefor and his recommendation thereon to the Director of Selective Service.

(f) The name of any physician, dentist or facility may be added to or removed from the record of designated physicians, dentists or facilities by the Director of Selective Service, either with or without a recommendation from a State Director of Selective Service.*

§ 661.22 *Schedule of fees for the Selective Service System.* The Director of Selective Service, from time to time, will publish and circulate schedules of fees which will state the maximum amounts allowable for the services of any physician, dentist or facility in remedying the defects of a registrant. These amounts will in no case be exceeded unless specifically authorized under instructions issued by the Director of Selective Service. When services not contained in the schedule of fees are necessary, such services may be authorized and the fees to be paid therefor in each instance fixed by the Director of Selective Service. Payment will not be authorized for any services rendered in remedying the defects of a registrant which are not authorized in accordance with instructions contained in this part, unless payment for such services is specifically approved by the Director of Selective Service either prior to or subsequent to the performance of such services.*

§ 661.23 *Procedure for payment of fees.* Bills for payment of fees authorized to be charged for services rendered in remedying the defects of a registrant should be certified in the manner prescribed in § 608.5 and presented, in triplicate, to the local board, which, if it finds that the authorized services have been performed, will indicate its approval on the original and both copies of the bill, retain one copy thereof, and forward the original and second copy thereof to the State procurement officer. In vouchering such bills, the State procurement officer shall use Public Voucher for Purchases and Services Other Than Personal (Standard Form No. 1034), which will be prepared in the manner prescribed in § 608.31.*

Jan. 17, 1942.

LEWIS B. HERSHEY, *Director.*

[F. R. Doc. 42-580; Filed, Jan. 20, 1942; 11:58 a. m.]

VACCINATION AGAINST TYPHUS FEVER, CHOLERA AND PLAGUE

Circular Letter No. 3

GENERAL PROVISIONS

The War Department has directed (section III, War Department Circular No. 4, dated Jan. 6, 1942):

(a) That all military personnel stationed in or traveling through Asia, Africa, continental Europe or other areas where danger from epidemic typhus fever exists will be immunized with typhus vaccine as prescribed by the Surgeon General.

(b) That all military personnel stationed in or traveling through Asia or other regions where cholera is known to be present in endemic or epidemic form will be immunized with cholera vaccine as prescribed by the Surgeon General.

(c) That all military personnel under serious threat of exposure to epidemics of human bubonic or pulmonic plague will be immunized with plague vaccine as prescribed by the Surgeon General.

INSTRUCTIONS CONCERNING VACCINATIONS

The following instructions will govern the use of typhus, cholera and plague vaccines:

(a) *Typhus Fever.*—1. Type and Source of Typhus Vaccine: The typhus fever vaccine to be used for the

immunization of military personnel will be of types approved by the Medical Department. At present the approved vaccine consists of a suspension of killed, louse-borne, epidemic typhus rickettsiae prepared by the Cox yolk-sac culture method. The vaccine may be procured in 20 cc. vials by requisition through regular Medical Department supply channels.

2. Initial Vaccination: This will consist of three injections of the vaccine, 1 cc. each, administered subcutaneously, with intervals of from seven to ten days between injections.

3. Subsequent Vaccinations: A stimulating dose of 1 cc. of typhus vaccine may be administered every four to six months as long as serious danger of infection is present. Other 1 cc. doses of typhus vaccine may be given whenever in the opinion of the surgeon this additional stimulation of immunity is indicated.

(b) *Cholera.*—1. Type and Source of Cholera Vaccine: The vaccine to be used will be of a type approved by the Medical Department. The vaccine now approved consists of a suspension of 8,000 million killed cholera vibrios (*V. comma*) per cubic centimeter. It may be

procured in 20 cc. vials by requisition through regular Medical Department supply channels.

2. Initial Vaccination: This will consist of two subcutaneous injections of cholera vaccine with an interval of from seven to ten days between the injections. The first dose shall consist of 0.5 cc. and the second dose shall consist of 1 cc. of the vaccine.

3. Subsequent Vaccinations: A stimulating dose of 1 cc. of cholera vaccine may be administered every four to six months as long as serious danger of infection is present. Other 1 cc. doses of cholera vaccine may be given whenever in the opinion of the surgeon this additional stimulation of immunity is indicated.

(c) *Vaccination Against Plague.*—1. Type and Source of Plague Vaccine: The vaccine supplied by the Medical Department consists of a suspension of 2,000 million killed plague bacilli per cubic centimeter. It may be procured in 20 cc. vials by requisition through regular Medical Department supply channels.

2. Initial Vaccination: This will consist of two subcutaneous injections of plague vaccine with an interval of from seven to ten days between injections. The first dose shall consist of 0.5 cc. and the second dose shall consist of 1 cc. of the vaccine.

3. Subsequent Vaccinations: Additional 1 cc. doses of plague vaccine may be administered whenever in the opinion of the surgeon additional stimulation of immunity is indicated.

OPPORTUNITY TO PREMEDICAL AND MEDICAL STUDENTS FOR APPOINTMENTS AS ENSIGNS IN CLASS H.-V. (P.) U. S. NAVAL RESERVE

The Secretary of the Navy recently approved a change in Navy regulations whereby it is now possible for those premedical students who have been accepted for entrance to, and all medical students in, class A medical colleges to be appointed in the United States Naval Reserve in class H.-V. (P.), provided they meet the physical and other requirements for such appointment.

Students who are acceptable will be given provisional commissions as Ensigns, and it is the policy of the Bureau of Medicine and Surgery not to nominate such officers for active duty until after they have completed their prescribed medical studies and shall have served one year's satisfactory internship in a civilian hospital accredited for intern training, or shall have been accepted as Acting Assistant Surgeon in the Navy for intern training.

On graduation, and when the bureau has been informed of this fact by the dean, commissions as Lieutenant (junior grade) M. C.-V. (G.), U. S. N. R., will be issued to provisional Ensigns and, after serving their internship in non-naval hospitals, they will be nominated for active duty. Application for, or acceptance of, either a provisional or a permanent commission in the Naval Reserve does not preclude the possibility of applying for a commission in the Medical Corps of the regular Navy. Persons affiliated with the Naval Reserve are not subject to induction into Army service by action of local Selective Service boards.

Navy regulations require that all applications for appointments in the Naval Reserve be filed with the commandant of the naval district in which the applicant resides. The address of the commandant of one's district may be obtained from the dean of one's college.

Application forms may be obtained from the dean's office or from some one designated by him on request from the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., or from the commandant of one's naval district. When the application form has been properly completed, it, together with the other credentials indicated on the application form, should be mailed to the commandant of the naval district. He will

MISCELLANEOUS

(a) *Storage and Shipment.*—The storage and shipment requirements of typhus, cholera and plague vaccines are the same as for triple typhoid vaccine.

(b) *Records of Vaccination.*—When military personnel are vaccinated against typhus, cholera or plague, records in duplicate will be made on MD form 81, Immunization Register. Disposition of these records will be in accordance with paragraph 6, AR 40-215.

(c) *Interval Between Doses.*—The prescribed time interval between doses of these vaccines should be adhered to as closely as possible; but, when this cannot be done, the missed dose or doses should be administered as soon as possible and a new series should not be started.

(d) *Efficacy of Vaccination.*—It is imperative to realize that vaccination alone is not adequate for the prevention of typhus, cholera or plague. The immunity conferred by these vaccines is incomplete and probably of relatively short duration. The practice of vaccination should therefore be considered an adjunct to the control measures prescribed in AR 40-225, AR 40-230, and such other special control measures as may be recommended by the surgeon of the force concerned.

By order of the Surgeon General:

JOHN A. ROGERS, M.D.,
Lieutenant Colonel, M. C.,
Executive Officer.

give instructions relative to obtaining a physical examination, finger prints, and so on.

In the case of a premedical student, it is necessary to enclose with the application for appointment a statement, signed by the dean of a medical college, to the effect that the applicant has been accepted as a first year medical student in a class A school for the next entering class.

It is the understanding of the Bureau of Medicine and Surgery that Selective Service boards will accept a statement from the commandant of the naval district to the effect that the application is on file as basis for deferment until the application has received final action.

PRICES OF SALICYLIC ACID AND THEOBROMINE

The Office of Price Administration, Washington, D. C., of which Leon Henderson is administrator, announced on January 20 that the establishment of maximum prices on salicylic acid and theobromine would be discussed with manufacturers and distributors at a conference called for January 21. The two additional products were added to the conference subjects because of the close relationship of salicylic acid to acetylsalicylic acid and theobromine to caffeine, because discussion of the additional products might better suit the convenience of the manufacturers and avoid calling further conferences, and also because the Office of Product Management had received reports that some supplies of these products had been offered at prices greatly in excess of prevailing prices.

LIEUTENANT COLONEL MORGAN ORDERED TO ACTIVE DUTY

Dr. Hugh J. Morgan, Nashville, Tenn., a lieutenant colonel in the medical corps reserve, has been called to active duty as head of the subdivision of medicine, professional services division, in the Office of the Surgeon General, U. S. Army, Washington, D. C., the War Department announced, January 20. Colonel Morgan has been on the staff at Vanderbilt University, Nashville, since 1924. During the first world war he served in the American Expeditionary Forces, first as a private and later as a first lieutenant in the medical corps.

ORGANIZATION SECTION

THE PHYSICIAN'S FEDERAL INCOME TAX—1942

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION

In view of the fact that March 15 falls on a Sunday this year, income tax returns must be filed on or before March 16, unless an extension of time for filing has been granted.

While the Revenue Act of 1941 did not basically change the structure of the existing income tax act, it did lower exemptions, increase surtax rates and in many other ways effect changes the overall result of which will be a sharp increase in the total tax that physicians and other taxpayers will be required to pay. The basic rate remains the same, 4 per cent on net income in excess of allowable exemptions and credits. The surtax this year is imposed on the first dollar of net income above the personal exemption and credit for dependents. The surtax rate is 6 per cent on the first \$2,000 and 9 per cent on the second \$2,000, with a constant increase in the rate for incomes in the higher brackets.

The earned income credit remains in the law and as heretofore may be claimed in connection with the normal tax but not in connection with the surtax. The special 10 per cent defense tax that was applicable last year has been eliminated as such.

A departure from previous practice is to be found in the provision for a simplified tax schedule for use by taxpayers having gross incomes of \$3,000 or less derived wholly from salaries, wages, other forms of compensation for personal services, dividends, interest, rents, annuities or royalties. The use of the simplified form is optional. If the taxpayer has no deductions it will be to his advantage to use this form. If he has deductions he should tentatively figure the tax under both the regular method and the optional method and use whichever method results in the smaller tax.

WHO MUST FILE RETURNS

In General.—1. Returns must be filed by every unmarried person and by every married person not living with spouse, if gross income during 1941 was \$750 or more.

2. Returns must be filed by every married person who lived with spouse, if gross income during 1941 was \$1,500 or over. If both husband and wife had income and their combined gross income was \$1,500 or over, they must either file separate returns or, if both are citizens or residents of the United States and if they were living together at the end of the taxable year, they may file a joint return. If a person was married and lived with spouse for only part of 1941, special rules apply with respect to the filing of returns, and physicians who come within this classification should read carefully the instructions given on the tax return blanks.

If the status of a taxpayer, so far as it affects the personal exemption or credit for dependents, changed during the year, the personal exemption and credit must be apportioned, under rules and regulations prescribed by the Commissioner of Internal Revenue with the approval of the Secretary of the Treasury, in accordance with the number of months before and after

such change. For the purpose of such apportionment a fractional part of a month should be disregarded unless it amounts to more than half a month, in which case it is to be considered as a month.

As a matter of courtesy only, blanks for returns are sent to taxpayers by the collectors of internal revenue, without request. Failure to receive a blank does not excuse any one from making a return; the taxpayer should obtain the necessary blank from the local collector of internal revenue.

Physicians in Military or Naval Service.—The fact that a physician may be in service does not of itself excuse a failure to file a return, for the income tax act applies to persons in service as well as to persons engaged in civilian activities. Physicians who have been inducted into service, therefore, should if at all possible file complete returns before the deadline. While, unfortunately, definite regulations have not been issued to cover the situation, it is understood that, if because of the inaccessibility of necessary records a physician in service is unable to file a complete return, he may file a tentative return on which he must estimate his income, deductions and tax as best he can and indicate on the return his reasons for following this procedure. He will be required at a later date to file a complete return, and necessary adjustments in the tax will be made.

If a physician in service is on duty outside the United States, the general regulations promulgated by the Bureau of Internal Revenue provide for an extension of time for filing a return up to and including the fifteenth day of the sixth month following the close of the tax year. In all such cases an affidavit must be attached to the return, stating the cause of the delay in filing.

GROSS AND NET INCOMES: WHAT THEY ARE

Gross Income.—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, assuming that the return is made on a cash receipts and disbursements basis, plus such money as he has received as profits from investments and speculation and as compensation and profits from other sources.

If a physician receives a salary as compensation for services rendered and in addition thereto living quarters or meals, the value to the physician of the quarters and meals so furnished ordinarily constitutes income subject to tax. If, however, living quarters or meals are furnished for the convenience of the employer, the value thereof need not be computed and added to the compensation otherwise received by the physician. As a general rule, the test of "convenience of the employer" is satisfied if living quarters or meals are furnished to a physician who is required to accept such quarters and meals in order to perform properly his duties. For example, if a physician employed by a hospital is subject to immediate service at any time during the twenty-four hours of the day and therefore cannot obtain

quarters or meals elsewhere without material interference with his duties and on that account is required by the hospital to accept the quarters or meals furnished by it, the value thereof need not be included in the gross income of the physician.

Net Income.—Certain professional expenses and the expenses of carrying on any enterprise in which the physician may be engaged for gain may be subtracted as "deductions" from the gross income, to determine the net income on which the tax is to be paid. An "exemption" is allowed, the amount depending on the taxpayer's marital status during the tax year as stated before. These matters are fully covered in the instructions on the tax return blanks.

Earned Income.—In computing the normal tax, but not the surtax, there may be subtracted from net income from all sources an amount equal to 10 per cent of the earned net income, except that the amount so subtracted shall in no case exceed 10 per cent of the net income from all sources. Earned income means professional fees, salaries and wages received as compensation for personal services, as distinguished from receipts from other sources.

The first \$3,000 of a physician's net income from all sources may be regarded under the law as earned net income, whether it was or was not in fact earned within the meaning set forth in the preceding paragraph. Net income in excess of \$3,000 may not be claimed as earned unless it in fact comes within that category. No physician may claim as earned net income any income in excess of \$14,000.

PHYSICIANS IN MILITARY OR NAVAL SERVICE

As previously pointed out, physicians in service are as much subject to the income tax law as are physicians engaged in civilian practice. The service pay of such physicians must be reported as income. Commutation of quarters and rental value of quarters occupied by medical officers, however, are not taxable income.

If the ability of physicians in service to pay income taxes is materially affected by such service, payment of the tax falling due before or during the service may be deferred for a period extending not more than six months after termination of service. This deferment is authorized by section 513 of the Soldiers' and Sailors' Civil Relief Act of 1940 and applies to all members of the Army, Navy, Marine Corps and Coast Guard, and to all officers of the United States Public Health Service detailed by proper authority for duty either with the Army or Navy, on active duty or undergoing training or education under the supervision of the United States preliminary to induction into service. This does not apply to the tax imposed on employers by section 1400 of the Federal Insurance Contributions Act.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for

office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equipment, "the useful life of which is short," generally less than one year, may be deducted; but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment, such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation reductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price or, if purchased before March 1913, either its fair market value as of that date or its original cost.

whichever may be greater. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in his individual case.

In a Treasury Decision, approved Feb. 28, 1934, No. 4422, it was held, among other things, that:

1. The cost to be recovered shall be charged off over the useful life of the property.

2. The reasonableness of any claim for depreciation shall be determined on the conditions known to exist at the end of the period for which the return was made.

3. Where the cost or other basis of the property has been recovered through depreciation or other allowances, no further deduction for depreciation shall be allowed.

4. The burden of proof will rest on the taxpayer to sustain the deduction claimed.

5. The deduction for depreciation in respect to any depreciable property for any taxable year shall be limited to such ratable amount as may reasonably be considered necessary to recover during the remaining life of the property the unrecovered cost or other basis.

Particular attention is called to the last of the foregoing provisions. If, in prior years, rates have been claimed which, if continued, will fully depreciate the cost, less salvage, before the end of its useful life, based on conditions now known, a reestimate of the remaining useful life should now be made and the portion of the cost that had not been depreciated at the beginning of the year 1941 (for a return for the year 1941) should be spread over this reestimated life.

Medical Dues.—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study.—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses.—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

Automobiles.—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeurs' wages, and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct

depreciation or operating expenses; he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

MISCELLANEOUS

Contributions to Charitable Organizations.—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. A physician may not, however, deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

Bad Debts.—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

Taxes.—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible; but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk, and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income.

Physicians may deduct state gasoline taxes if such taxes are imposed on the consumer or user rather than on the seller or distributor. The same is true with respect to state sales taxes. In some states these taxes are imposed on the seller and, even though they may be passed on to the buyer, the latter may not deduct them. The federal gasoline tax is not imposed on the user and hence cannot be deducted by him.

State income and use taxes are deductible; federal income taxes are not. Among the federal taxes that a physician may deduct are those on admissions, dues, initiation fees, safety deposit boxes and tax on telegraph, telephone, cable and radio messages. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes, and not to raise revenue, the fee may not ordinarily be deducted as a tax. If such fees, however, are classifiable as a business expense, they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business expense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold

the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Equipment Necessitated by Military Service.—The cost of equipment of an Army officer to the extent only that it is especially required for his profession and does not merely take the place of articles required in civilian life is deductible. Accordingly, the cost of a sword has been held to constitute an allowable deduction, but the cost of a uniform is considered a personal expense and hence not deductible.

Laboratory Expenses.—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes.—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense

and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums.—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits.—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles.—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold. Entries on the physician's account books should in such cases show charges for services separate and apart from charges for spectacles, etc.

OFFICIAL NOTES

THE ATLANTIC CITY SESSION

Applications for Hotel Reservations

A list of Atlantic City hotels, together with the rates for rooms, may be found on advertising page 34 of this issue of *THE JOURNAL*. With this list will be found an application form that may be used to secure reservations through the Subcommittee on Hotels of the Local Committee on Arrangements. This application form may be clipped and, when it is properly filled in, should be sent at once to Dr. V. Earl Johnson, Chair-

man of the Subcommittee on Hotels, The Convention Bureau, 16 Central Pier, Atlantic City, N. J.

Those who expect to attend the annual session of the American Medical Association should send in their applications at the earliest possible time. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be assured if the desired reservation cannot be had at the hotel of preference. It will greatly expedite matters if requests for reservations are addressed directly to Dr. Johnson.

MEDICAL LEGISLATION

STATE MEDICAL LEGISLATION

New York

Bill Enacted.—A. 40 has been enacted as Chapter 1 of the Laws of 1942, providing that nothing in the nursing practice act shall be construed as prohibiting the practice of nursing by other than registered or practical nurses until one year following the cessation of hostilities.

Bills Introduced.—S. 66 and A. 61 propose that a cause of action to recover damages for malpractice shall not be deemed to have accrued until the discovery by the injured person of the facts constituting the malpractice but that in no event can such an action be instituted after six years from the occurrence of the alleged malpractice. S. 111 and A. 11 propose that every physician attending or treating a case caused by an automobile accident, or whenever such case is treated in a hospital, sanatorium or other institution, the manager, superintendent or other person in charge, shall report such case at once to the police authorities of the city, town or village where such physician, hospital, sanatorium or institution is located. S. 125 proposes that the provisions of the New York State unemployment compensation act shall apply with respect to persons employed in the preparation and handling of food for human consumption in hospitals and educational institutions which at this time are exempt from the provisions of the act. A. 83 proposes that in any city of a million or more population there shall be maintained by the board of education a permanent staff of physicians, dentists, dental hygienists and nurses for the periodic examination and promotion of the health of the school children. A. 153

proposes to authorize the state department of health to render free of charge to all inhabitants of the state "all medical, surgical, dental, nursing care and treatment and all other services and facilities known to science and designed or adapted for use in all cases of sickness, accidents and childbirth . . . maintenance in hospitals, the furnishing and supplying without cost of medicines, drugs" and all other necessary equipment and supplies. The bill proposes to increase the staff of the department so as to include all registered physicians, dentists, pharmacists, technicians, research and laboratory workers and all other persons practicing allied professions who elect to serve and to pay them salaries in accordance with the schedule fixed in the bill. The department is to be authorized to exercise exclusive control over all public hospitals and is to have complete supervisory powers over all private hospitals and the staff, officers and employees thereof. A. 155 proposes to require a physician's certificate as to physical condition as a condition prerequisite to the issuance or renewal of operators' and chauffeurs' licenses to operate motor vehicles.

Rhode Island

Bill Introduced.—H. 536 proposes to create the Special Health Insurance Fund Commission to study sickness and health in the state and all pending federal legislation with the purpose in view that, if Congress should initiate a federal health insurance law which will require appropriate action by state legislatures, the commission will be in a position to recommend to the general assembly such action as it deems expedient for the adequate medical care of the population of the state.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Courses in Pediatrics.—Thirteen physicians selected from rural areas of California, Nevada, Utah and Arizona are enrolled in an intensive refresher course at the University of California Medical School, San Francisco, on the care of infants and children, according to the university's *Clip Sheet* of January 13. Designed for general practitioners, the course is being given by Dr. Amos Christie, associate professor of pediatrics, and members of the medical school staff, in cooperation with the state department of public health and the California Medical Association. The department of public health of the state from which the physician comes pays his tuition and traveling expenses, these funds being obtained from the children's funds of the social security act. The program is closely connected with the circuit rider plan of the university and the California department of health. Under this plan Dr. Sydney E. Sinclair, associate in pediatrics at the medical school, travels over California as an agent of the state department of health, acting as a consultant for county medical societies, individual physicians and groups involved in the care of young children.

DISTRICT OF COLUMBIA

Society Adopts Plan for Periodic Examination.—The Medical Society of the District of Columbia has approved a project whereby periodic health examinations will be available to the District general population at a set fee of \$5 and at a meeting on January 7 incorporated the program as a permanent and integral part of the society's activities. The examination will not be a diagnostic procedure but one to determine the physical fitness of apparently healthy persons. Physicians themselves are urged to participate in the program in order that they too may be given physical examinations. Cooperation of the Health Security Administration and local medical schools is being sought so that persons entitled to free medical service will receive periodic health examinations in clinics of local hospitals. In setting up the project, "Periodic Health Examinations—A Manual for Physicians," published by the American Medical Association, was used as a basis for the study by the committee on public health of the District society.

ILLINOIS

Personal.—Dr. Edwin S. Hamilton, Kankakee, was recently appointed a member of the medical examining committee of the state department of registration and education, succeeding Dr. Milton M. Portis, Los Angeles, who resigned.—Dr. Benjamin L. Sargent, Park Ridge, has been appointed health officer of Park Ridge to succeed the late Dr. Irvin J. Pascoe, Park Ridge.

Chicago

The Sixth Fenger Lecture.—Dr. James P. Simonds, professor of pathology, Northwestern University Medical School, will deliver the sixth Christian Fenger Lecture of the Institute of Medicine and the Chicago Pathological Society at the Palmer House, February 27. His subject will be "Clinical Correlation of the Anatomic and Functional Pathology of Renal Disease."

Society News.—Dr. Charles Gordon Heyd, New York, will address the Chicago Medical Society, February 18, on "Consideration of the Hepatorenal Syndrome," and Dr. Andrew C. Ivy, "Rationale of Bile Salt Therapy."—The Chicago Laryngological and Otological Society will be addressed, February 2, by Drs. Noah D. Fabricant on "Present Status of Nasal Medication"; Hans Brunner, "Otitic Brain Abscess," and Arnold A. Zimmerman, Ph.D., "Origin and Development of Pharyngeal Lymphoid Structures."

IOWA

Personal.—Dr. Thomas A. Burcham, Des Moines, was chosen on December 17 as chairman of the state medical advisory council for civilian defense, a subcommittee of the state industrial defense commission.—Dr. Celia A. McNeely, formerly of Corinth, N. Y., has been appointed physician in charge of the girls' division of the state school at Glenwood.

State Ophthalmologic Meeting.—Dr. Stephen A. O'Brien, Mason City, was chosen president-elect of the Iowa Academy of Ophthalmology and Otolaryngology at its annual meeting in Iowa City, December 5, and Dr. Thomas R. Gittins, Sioux City, was installed as president. Dr. Carl A. Noe, Cedar Rapids, is secretary-treasurer. Dr. Harris P. Mosher, Marblehead, Mass., Walter Augustus Lecompte professor of otology and professor of laryngology, emeritus, Harvard Medical School and the graduate school, Boston, was guest speaker at the session.

State Society Reviews Educational Activities.—The speakers' bureau of the Iowa State Medical Society has published a report of its activities for 1941. Eleven postgraduate courses were held during the year, including one which began in the fall of 1940, comprising seventy lectures. Ninety-one medical talks were given before various lay organizations throughout the state. Of the thirty-six scientific recordings sent out during this period, twenty were meetings of county medical societies and sixteen for hospital staff and medical club meetings. A new type of educational activity this year was the cooperation with the division of industrial hygiene of the state department of health and the state medical society's committee on industrial health in sponsoring nine special institutes on industrial hygiene in key cities throughout the state. Fifty-two radio broadcasts were given and one thousand, seven hundred and eleven copies of the manuscripts were mailed out in response to requests received, an increase of about 75 per cent in the number of talks requested by radio listeners. In connection with each broadcast, an announcement concerning smallpox was made in an effort to reduce the incidence of the disease in Iowa.

KENTUCKY

Mother of First Male Quintuplets in America Dies.—

Mrs. Elizabeth Lyon, aged 84, mother of the first male quintuplets born in the United States, died on December 29 at the home of her son Martin Lyon near Kevil, Ky. On April 29, 1896, Mrs. Lyon gave birth to five sons in Mayfield. They were named Matthew, Mark, Luke, John and Paul. All were normal and weighed between 4 and 5 pounds at birth. The first one died four days after birth and the last one died thirteen days after birth. They were buried in the War Memorial Museum, Washington, D. C. The late Dr. Samuel J. Mathews, Mayfield, was the physician who attended Mrs. Lyon. A newspaper, in commenting on Mrs. Lyon's death, stated that "crowds came from as far away as Memphis and dropped more than \$600 in a glass jar to help the family." Two passenger trains that passed Mayfield in the daytime would each stop across from the Lyon home so that passengers might alight and see the quints, who were placed on the porch in "mosquito netting" covered cradles.

MARYLAND

Portrait of "The Musketeers of Medicine."—A life-size portrait of Drs. Guy L. Hunner, Thomas S. Cullen and Samuel Griffith Davis Jr., all of Baltimore, has been placed in the waiting room of the Church Home and Infirmary, Baltimore, the gift of the graduate nurses of the institution. The portrait is the work of Mrs. I. Hunner Parsons, daughter of Dr. Hunner. The three physicians are known as the "Three Musketeers" of medicine because of their close association for more than forty years with the staff of the Church Home. Dr. Hunner is adjunct professor emeritus of gynecology and Dr. Cullen is professor emeritus of gynecology at Johns Hopkins University Medical School, while Dr. Davis is professor of anesthesia at the University of Maryland School of Medicine. Dr. Cullen is a former member of the Board of Trustees of the American Medical Association.

MASSACHUSETTS

New Cancer Arrangement at Massachusetts General.—On January 15 the inpatient and outpatient services for the diagnosis and treatment of cancer of the Collis P. Huntington Hospital, Boston, were transferred to the Massachusetts General Hospital, Boston. As soon as facilities have been made available, a substantial part of the research work in cancer at Huntington Memorial will also be transferred to the general hospital (THE JOURNAL, January 3, p. 58). The action was taken because of the belief of Harvard University and Massachusetts General Hospital that the care and treatment of medical specialties can more efficiently be handled as part of a large institution of general scope than in smaller individual units.

Grant to Biologic Library.—The Marine Biological Laboratory, Woods Hole, has received a grant of \$25,000 from the Carnegie Corporation of New York to be used primarily to complete back sets of journals and to add to its collection of books, according to *Science*. The gift will enable the library to provide investigators with complete runs of all the important biologic journals and of many covering chemistry, physics, paleontology, radiology, medicine and other sciences allied to biology. Under a gift from the Rockefeller Foundation in 1940, the library is now located in a new building which more than doubles the original space. In 1920 the number of serials received was 153; now it is 1,257. The collection of reprints has increased from 8,500 to 120,000.

MISSOURI

Society News.—Dr. Clarence A. Mills, Cincinnati, discussed "Climate and Weather as Health Factors" before the Kansas City Academy of Medicine, December 12.—Dr. Richard G. Helman, Kansas City, discussed eclampsia before the Nodaway-Atchison-Gentry-Worth Counties Medical Society, December 1, in Maryville.—Dr. Ora Earl Whitsell, St. Joseph, discussed "Foreign Body in the Air and Food Passages," January 7, before the Buchanan County Medical Society, St. Joseph.—Dr. James C. Sargent, Milwaukee, discussed "Common Injuries Involving the Urinary Tract" before the St. Louis Medical Society, December 16, under the auspices of the St. Louis Urological Society.

Ear, Nose and Throat Meeting.—The middle section of the American Laryngological, Rhinological and Otolological Society presented the following program at a meeting in St. Louis, January 21:

- Dr. Joseph C. Beck, Chicago, Ways and Means of Studying Gross Pathology of Otolaryngology and Its Borderlines.
- Dr. Thomas Roy Gittins, Sioux City, Headache and Neuralgia.
- Dr. Samuel Iglauer, Cincinnati, Autopsy Studies of a Case of Tuberculous Peripharyngeal Abscess.
- Dr. Dean M. Lierle, Iowa City, Arteriovenous Aneurysm: Report of a Case Involving the Transverse Facial Artery and Vein.
- Dr. Carl H. McCaskey, Indianapolis, Upper Respiratory Infection of a Fulminating Character Requiring Tracheotomy.
- Dr. Sam E. Roberts, Kansas City, Ear, Nose and Throat Conditions Due to Disturbed Nutrition.
- Dr. John J. Shea, Memphis, Tenn., Office Treatment of Vertigo.
- Dr. Jacob Marion Sutherland, Detroit, Medical Research and War Problems: Forewarned Is Forearmed.

NEW MEXICO

Changes in Health Personnel.—Dr. Stuart W. Adler, Albuquerque, has been appointed director of the division of maternal and child health of the state department of public health, succeeding Dr. Hester B. Curtis, now of Charleston, W. Va.—Dr. Roy H. Wilson, Clovis, recently resigned as health officer of district number 10.

Public Health Election.—Dr. Alvin R. Clauser, Albuquerque, was chosen president-elect of the New Mexico Public Health Association at its recent sixteenth annual meeting in Gallup, and Dr. Frank C. Diver, Raton, was installed as president. Dr. Harrison Eilers, Las Vegas, is vice president, and Frances Fell, Santa Fe, secretary-treasurer.

NEW YORK

Health Department Honors Retiring Physicians.—The Rochester Department of Health gave a dinner recently in honor of Dr. Joseph Roby, since 1904 deputy health officer, and Dr. James T. McGovern, since 1900 health physician, to mark their retirement, both having reached the compulsory age limit for retirement. Dr. Roby was presented with a wrist watch by employees of the health department and Dr. McGovern was presented with a traveling bag.

Grant for Work on Rheumatic Fever.—An award of \$1,000 has been made by the Borden Company to Irvington House, Irvington, to assist in its study and treatment of rheumatic fever. The researches are under the direction of Dr. Ann G. Kuttner, Irvington, resident medical director, with the guidance of a medical advisory board, of which Dr. John Murray Steele, New York, is director. About one hundred young underprivileged patients are cared for at Irvington House.

New York City

Alumni Day at New York University.—The date of the annual "Alumni Day" at New York University College of Medicine has been changed back to the usual dates of February 20 and 21, according to an announcement from the secretary, Dr. Marshall S. Brown Jr. A dinner at the Hotel Essex will open the program Friday; a scientific session will make up the second day's activities.

Courses at Mount Sinai Hospital.—The second semester of postgraduate courses will open at Mount Sinai Hospital, February 2, to continue through March 28, covering bacteriology, cardiology, gynecology, general medicine, medical statistics, neurology, ophthalmology, pathology and pediatrics. A course on radiology will be given in affiliation with Columbia University College of Physicians and Surgeons.

Dedication of New Dispensary.—The new million dollar Dispensary Building of Kings County Hospital, Brooklyn, was recently dedicated. Among those participating were Dr. Joseph Tenopyr, chairman, executive committee of the medical board of the hospital; Dr. Maurice J. Dattelbaum, president of the Medical Society of the County of Kings and the Academy of Medicine of Brooklyn; Dr. Willard C. Rappleye, commissioner of hospitals, and Mayor Fiorello H. La Guardia.

Personal.—Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research has been elected an honorary fellow of Trinity Hall, University of Cambridge, where he was awarded the honorary degree of Sc.D. He was Linacre lecturer there in 1929.—Dr. Harry A. La Burt, assistant physician of Harlem Valley State Hospital at Windale, has been named superintendent to succeed Dr. John R. Ross, who has been transferred to Hudson River State Hospital at Poughkeepsie.—Dr. Donald E. Cameron, Albany, N. Y., has been appointed a member of the state board of psychiatric examiners.

Annual Regional Meeting on Social Hygiene.—The Coordinating Council of the five county medical societies, the New York Academy of Medicine and the five medical schools in New York will participate in the tenth annual Regional Conference on Social Hygiene, to be held at the Hotel Astor on February 4 under the auspices of the social hygiene committee of the New York Tuberculosis and Health Association in cooperation with local public and private educational health and welfare agencies. The speakers at a session on social hygiene and national defense will include Dr. Raymond A. Vonderlehr, assistant surgeon general, division of venereal diseases, U. S. Public Health Service, Washington, D. C.; Capt. Charles S. Stephenson, M. C., U. S. Navy, in charge of the division of preventive medicine, Washington, D. C.; Dr. Edward S. Godfrey Jr., state health commissioner, Albany, and Major John A. Warner, superintendent of the state police. Other speakers on the program will include Drs. Ross T. McIntire, surgeon general of the U. S. Navy, Robert M. Lewis, New Haven, Conn., and Robert C. Clothier, LL.D., president, Rutgers University, New Brunswick, N. J. The program has been divided into the following sessions: the nurse and social hygiene, firm foundations for family living, social hygiene films and national defense, a panel discussion on venereal diseases, the United Service Organizations program and social hygiene, current delinquency problems and youth today and tomorrow—a challenge.

OHIO

Changes in Health Officers.—Dr. Chester S. Heimlich, Attica, has resigned as health officer of Seneca County to devote his full time to private practice, it is reported.—Dr. Homer S. West, St. Clairsville, has been appointed health commissioner of Belmont County, filling the vacancy that occurred when Dr. William B. Bailly, now of Morgantown, W. Va., resigned several months ago.

Postcollegiate Assembly Canceled.—The Ohio State University College of Medicine, Columbus, has canceled its ninth annual postcollegiate assembly, which had been announced for March 5-7, because of the present war emergency. The faculty of the medical school believes it should render every service to the program of medical military and civilian defense and will cooperate, in an educational way, with the Ohio State Council of Defense and other war to victory efforts.

Library Given to Academy of Medicine.—The late Dr. Martin Stamm, Fremont, was posthumously made an honorary member of the Toledo Academy of Medicine recently, and plans are under way to erect a plaque in his memory to be hung in the academy. The joint tribute marks the acknowledgment by the academy of a collection of medical books which Dr. Stamm had bequeathed to the Birchard Library in Fremont. The library in turn presented the collection to the academy of medicine.

Ten Years as President of County Society.—Dr. Edward F. Heffner was reelected president for the tenth consecutive year of the Auglaize County Medical Society at its meeting in Wapakoneta in December. Dr. Clyde W. Berry was chosen secretary. Dr. Charles C. Berlin had served the society for eleven years as secretary but contended that twelve years would be too long a term when the association had numerous good members able to fill the office. All are of Wapakoneta.

tary Service" will be discussed by Drs. Samuel J. Kopetzky, New York, George Baehr, New York, and Laurance D. Redway, Ossining, N. Y., and J. Roy Blayney, D.D.S., Chicago. "The Role of the Medical, Dental, Nursing Schools and Hospitals in Anticipating the Acceleration of Training" will be the subject of Drs. Joseph R. Darnall, Washington, D. C., Leonard G. Rowntree, Washington, D. C., and Fred C. Zapffe, Chicago.

Notice to Manufacturers of Glandular Preparations.—On Dec. 1, 1939, in a notice addressed to manufacturers of preparations of ovary, the Food and Drug Administration expressed the opinion that preparations of ovary recommended for oral administration which are devoid of the known active constituents of that gland are adulterated and misbranded if labeled in a manner implying that such active constituents are present. The same principle is applicable to preparations, recommended for oral use, of corpus luteum and "ovarian residue," and to preparations of various other glands including orchic, adrenal and pituitary. In particular there is no scientific evidence that preparations of the named glandular substances, except concentrated estrogenic extracts of ovaries, exhibit any physiologic or therapeutic effects when administered through the gastrointestinal tract. Some of the preparations of these glands intended for parenteral administration also have been found devoid of any significant activity. Any such inert preparation is regarded as misbranded unless reference on its labeling to the presence of such glandular constituents is accompanied by a forthright, conspicuously displayed statement to the effect that the article does not contain any known therapeutically useful constituent of the gland or glands mentioned. Further, there is no scientific evidence that prostate, pineal and mammary contain any therapeutically or physiologically active constituents. The labeling of articles purporting to be preparations of these glands should, in the opinion of the administration, bear conspicuously displayed statements to this effect. Section 201(n) of the Federal Food, Drug and Cosmetic Act requires, in effect, the revelation of such material facts. Labeling which merely disclaims responsibility of the manufacturer for activity of an article is not regarded as complying with this provision of the law.

LATIN AMERICA

Personal.—Dr. Mario L. Soto, La Plata, Argentina, has been appointed professor of pharmacology at the University of Buenos Aires; he will devote his time to research and will give up his clinical connections, *Science* reports.

Congress on Plastic Surgery.—The second Latin American Congress of Plastic Surgery will be held in Buenos Aires in October, the dates to be announced later. Two papers now being planned for discussion are "Labiovelopalatine Fissure" and "Plastic Reparation of Great Loss of Substances of the Face." The first subject will be discussed by Drs. Enrique Apolo, Héctor Marino and J. Delleplane Rawson and the second by Drs. Mario Kroeff, David Adler and Oscar Ivanissevich. Drs. Ivanissevich, Alejandro Ceballos and Enrique Finochietto, all of Buenos Aires, are members of the organizing committee in charge of the congress.

CORRECTIONS

Roentgen Therapy of Gas Bacillus Infection.—In the editorial with this title in *THE JOURNAL*, January 17, page 230, in the thirteenth line, the number 500 is erroneous with respect to the roentgen dose and it should have been 50. The sentence should read "From 50 to 100 roentgens per field should be given two to three times daily for a period of three to five days."

The Emigré Physician in America, 1941.—In the article with this title in *THE JOURNAL*, Nov. 29, 1941, page 1887, a paragraph begins with the statement "A bill was recently passed in California which would deny the license even to a California native son who happens to be a graduate of a foreign school, unless the country in which the school is located extends reciprocity to Americans." Dr. C. B. Pinkham, secretary of the California Board of Medical Examiners, has written to the National Committee for Resettlement of Foreign Physicians that the committee has been wrongly advised as to the legal interpretation of this portion of the California statutes and particularly as to that portion which reads "if the applicant is not a citizen of the United States." This phraseology exempts citizens of the United States from the requirement of what is referred to as "reciprocity."

Government Services

Community Expansion and Improvement Program

President Roosevelt has approved an appropriation of \$150,000,000 to provide through federal grants a general expansion and improvement program throughout the country. Under this setup hospitals, health centers, sanitary facilities, schools and recreation centers will be added to communities which, if left to their own resources to provide these needs, would be unduly burdened financially and which, because of increased defense activities, are in need of such additions. The federal grants are aimed to assist the local units in carrying out necessary improvements. Up to November 26 health centers and hospitals had been approved for twenty-three states, Hawaii and Alaska, and provision for sanitary facilities had been approved for thirty-four states and Hawaii and Alaska.

Recommendations Concerning Narcotics

According to an announcement from the Office of Civilian Defense, morphine is the only narcotic now being recommended for use by emergency field units. These units are related to hospitals and it is planned to give morphine only as ordered by physicians. It is hoped that local hospitals and physicians will not attempt to procure large stocks of the drug. The release pointed out that narcotics would be purchased centrally through the office of the surgeon general of the U. S. Army and would be allocated to communities as part of the supplies furnished by the Office of Civilian Defense. It was recommended that narcotics should not be stored in the same manner as other supplies which are stored in the emergency field units but should be placed in a warehouse of the licensed wholesaler from which it is purchased and requisitioned by the hospital and emergency field units through the regional medical officer. At the hospitals, narcotics should be locked in a place approved by the U. S. Commissioner of Narcotics or his agent until such time as the narcotic may be needed. It is urged that regional medical officers establish contact with the state chiefs of emergency medical service in their respective regions and request that this information be transmitted to local chiefs of emergency medical services and the hospitals.

Warning Against Cadmium in Cooking Utensils

Because of outbreaks of food poisoning, the Federal Security Agency has advised manufacturers against using cadmium, a substitute for aluminum, in plating cooking utensils and refrigerator containers. The Food and Drug Administration and the U. S. Public Health Service, following an investigation of outbreaks, have found that they were due to cadmium, which they said contained a poisonous substance causing severe illness when taken in food even in small amounts. The Federal Security Agency has conferred with representatives of the plating industry, and it is probable that this industry will cease using cadmium for food container purposes. At the same time the Office of Production Management has stated that it would not release cadmium for this use.

Five of the outbreaks, involving at least fifty persons, were traced to the consumption of frozen food which had either been chilled in refrigerators equipped with cadmium plated ice trays or served in cadmium plated metal containers. Symptoms of cadmium poisoning include acute gastritis, nausea, cramps, vomiting, diarrhea and weakness. Illness may occur within ten minutes after eating or drinking the contaminated food. As little as 15 parts per million of cadmium may cause acute symptoms. Foods containing acids are particularly apt to be affected. None of the recently reported cases resulting from the consumption of cadmium with foods have been fatal. Chronic poisoning, with severe damage to vital organs, will, however, result from repeated exposure. The difficulty of obtaining aluminum and materials used in making stainless steel has led to the use of cadmium, especially in repairing or replating household equipment.

Utensils in which cadmium has most frequently been detected are refrigerator ice trays, plated aluminum ware, water pitchers, meat grinders, and food choppers and mixers.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 13, 1941.

The Prevention of Hospital Infection of Wounds

The war has brought into prominence certain surgical problems which have been investigated by the Medical Research Council, which has produced valuable memoranda. Among these are the treatment of wound shock, the diagnosis and treatment of gas gangrene and emergency amputations, which have been summarized in previous letters to *THE JOURNAL*. The latest one, on the prevention of hospital infection of wounds, has been produced by the War Wounds Committee of the Council and the Committee of London Sector Pathologists, whose members include eminent surgeons and pathologists. They point out that recent prewar studies have revealed a low but definite incidence of hospital infection, indicating defects of aseptic technic. In war time the consequences are more obvious, because war wounds are more liable to infection and many of them, being infected before admission, provide an abundant reservoir of pathogenic bacteria. During this war several observers have recorded a high incidence of hospital infection. This memorandum is the outcome of a study of the problem in several hospitals. The bacteria which may infect wounds in a hospital include *Streptococcus pyogenes*, *Bacillus pyocyaneus*, coliform bacilli, the diphtheria bacillus and occasional anaerobic spore bearing bacilli. Commonest and most important are the pyogenic streptococci and staphylococci. The diphtheria bacillus rarely infects wounds. Hemolytic streptococci (most of which are *Streptococcus pyogenes*) normally live in from 5 to 30 per cent of human throats. *Staphylococcus pyogenes* normally lives in from 20 to 40 per cent of human noses and on 10 to 20 per cent of human skins. Hospital infection may be derived from throats, noses and skins, but a more important reservoir is in other wounds already infected. Contamination occurs by contact with soiled fingers, instruments and lotions, by infected droplets from the mouths and noses of those near when dressings are off and from the dust of the air of the ward. Contact is probably the commonest mode of infection.

Since wounds are protected from infection except when dressings are being done, "cross infection" should be easier to control than another kind of cross infection also found in hospitals—infection from the upper respiratory tract. The analogy between a wound and a culture on a Petri dish suggests the principle for the handling of wounds in the ward. The dresser, like the bacteriologist, works in an environment of infected dust and dirty objects, among which strict bacteriologic control must be maintained over a comparatively small area, which is exposed for the shortest possible time. In the ward a wound should be treated much as a bacteriologist treats a plate culture. The technic need not be as elaborate or as costly as that of the operating room.

Dressings which are extensive or complicated and which involve prolonged exposure and manipulation of the wound cannot be protected by the precautions which suffice for simpler dressings in the ward and should be done in a room set aside for the purpose. When dressings are in progress, precautions should be taken to keep the bacteria in the ward air as low as possible. One hour at least during which sweeping, dusting, bed making and other activities which raise dust are forbidden should precede the dressing. During the dressing and before it, while the trolley is being prepared, doors and windows are closed and traffic through the ward is stopped. Bedclothes are to be manipulated gently and slowly. Hands, whether wet or dry, scrubbed or unscrubbed, are to be regarded as in all circumstances dirty and should not be allowed to touch the wound

or anything which comes in contact with it. Sterile gloves are worn for dressings too complicated to be managed with forceps alone. Wounds are to be uncovered for the shortest possible time. The skin around the wound should be treated with the same care as the wound itself. It is easier to keep things sterile if they are dry. Hands and instruments should be dry, since, if they are wet, bacteria are readily washed from them into the wound. The most perfect dressing technic may not prevent infection unless the sterilizer, baths, utensils, floors and all ward accessories are properly cared for. When dressings begin the ward is closed to all nonessential traffic, windows and doors are shut, and all in the ward (except patients, provided they remain silent) don a mask. Surgeons, nurses or students suffering from upper respiratory inflammation of any kind must at once go off surgical duty and remain off until the inflammation has completely subsided. Convalescent carriers and healthy carriers, recognized by swabbing but not suffering from active inflammation, should remain off duty only while swabs yield profuse cultures. The danger of wound infection from droplets can be reduced to a minimum if all taking part in surgical work wear masks. Sterilization of instruments and equipment by boiling is preferable to chemical disinfection, because it is more reliable and less costly. But for certain purposes chemical disinfectant solutions are indispensable.

The Food Situation

In the House of Commons at the opening of a new session the prime minister, Mr. Churchill, surveyed our food situation. We had curtailed our food imports in favor of munitions, and our dietary was so curtailed that it was less varied and interesting, but it was sufficient for physical health, and he hoped soon to give more meat to workers who need it most. As a precaution we had amassed stocks of the bulky articles of our diet, which amounted to double what they were in September 1939. There had been a great expansion of the home production of food. In the short space of two years the area under crops had been increased by 45 per cent. Our corn harvest was 50 per cent greater than in 1939. We also had large crops of potatoes, sugar beet, fodder and roots. Despite lack of feeding stuffs we had well maintained our head of cattle, both dairy cows and meat cattle. Our people would have better Christmas dinners than last year, and dinners which would be more justified by the food position. It will thus be seen that the favorable reports on the food situation made in previous letters to *THE JOURNAL* are borne out. In a nutshell, we are not getting such food as we should like but what is sufficient for maintaining health and capacity for work.

THE FEEDING OF YOUNG CHILDREN

In consequence of the government food control, young children were probably never so well fed. The latest measure is the free distribution of fruit juices and cod liver oil to all children born after Jan. 1, 1940. This important new step to safeguard the health of very young children is being taken by the Ministry of Food in cooperation with the Ministry of Health. The Ministry of Food has requisitioned most of the last black currant crop, and the first issue will consist of black currant syrup and purée. When these have been used, concentrated orange juice—a lease and lend offering from the United States—will be available. Sufficient of either will be provided to insure that each child has an adequate daily supply of vitamin C.

Concurrently with both fruit essences, cod liver oil compound made from Icelandic oil will be issued in sufficient amount to insure a satisfactory intake of vitamins A and D. Distribution will be made through maternity and child welfare centers and food offices. Some 1,360,000 children will benefit. The object of the government is to build up the resistance of these young children before the onset of severe winter weather. After three or four months the scheme will be reviewed and a decision taken as to whether the scheme should be free to all.

Winter has reduced supplies of liquid milk, which will become progressively smaller for all but expectant and nursing mothers, children and persons in the hospital. This shortage will continue until February or March, but the priority classes mentioned are assured of their supplies. They number twelve million and will receive 40 per cent of the milk supply, while the rest of the population, thirty-two million adults, will receive 60 per cent. Cuts have been made in the supplies to catering establishments. The new milk movements branch of the Ministry of Food is endeavoring to equalize as far as possible supplies over the whole country. It has ready for distribution this month forty million cans of unsweetened condensed milk. The same amount will be available for December. The United States, Canada and New Zealand have sent us all the processed milk they could provide; in addition, twelve million cans of milk powder will be available through the grocers' shops.

Health Publicity

To encourage the taking of every possible precaution against illness during the autumn and winter the minister of health has decided, in collaboration with the Central Council for Health Education, to intensify health education activities. In particular, special efforts are being made to secure the cooperation of the public in reducing the spread of diseases caused by droplet infection, such as influenza and the common cold, as well as diphtheria, measles, whooping cough, cerebrospinal fever and tuberculosis. In normal times influenza and the common cold alone are responsible for between 30 and 40 per cent of the working hours lost in industry.

Show cards and posters (some eighty thousand in all, including reproductions of drawings by the artist H. M. Bateman) are exhibited in busses, street cars and underground trains, at main line railway stations, in chain stores and in the vestibules of cinemas. They are also exhibited in factories. They carry the message "Coughs and sneezes spread diseases. Trap the germs by using your handkerchief. Help to keep the nation fighting fit."

This campaign was opened by the chief medical officer of the Ministry of Health at a press conference. The minister of health has sent a circular embodying the facts to the local health authorities (county councils, county borough councils and maternity and child welfare authorities). He has asked them to cooperate in the campaign in every possible way. He has suggested that, in addition to providing facilities for displaying the posters, members and officers of the council may secure the publication of topical articles in the local press or arrange film shows. Copies of "Breath of Danger," a sound film recently made for health education to illustrate the dangers of unguarded coughing and sneezing, are available at the library of the Central Council for Health Education and will be issued on free loan to approved borrowers for nontheatrical showing. Finally, a three weeks display of posters on droplet infection is taking place in the windows of fifteen hundred stores and gas and electricity undertakings throughout the country.

Air Raid Precautions for Users of Radium

The minister of home security, in consultation with the Ministry of Health, has had under consideration the question of the safe custody, handling and transport of radium under war conditions. In addition to the radium held by hospitals under arrangements with the Radium Commission and King Edward's Hospital Fund for London, an appreciable amount is in the hands of small hospitals, physicians and commercial firms. The minister has decided that for the protection of the public it is necessary to bring to the notice of all who have the custody of radium the precautions which should be taken to avoid its dispersal by enemy action and the course to be followed in the event of its dispersal.

All radium exceeding 1 mg. in amount, not in actual use, should be kept in a bore hole or steel container of approved type. The bore hole should have a depth of about 50 feet, depending on the nature of the subsoil. It should be lined with steel tubing and have a diameter of 6, 8 or 10 inches, depending on the amount of radium to be stored. The bottom of the shaft should be cemented. At the ground level there should be a superstructure consisting of a concrete enclosure with a door fitted with winch and cable to raise or lower the radium receptacle.

The approved type of steel container consists of a block of mild steel, either round or square in section, with a central cavity and a screwed plug to seal this. The receptacle is protected by a layer of resilient material, such as cork or rubber, which is within the cavity. The wall thickness of the steel block must not be less than 3 inches. Not more than 350 mg. of radium should be kept in one steel container. In a hospital situated in a vulnerable area, not more than this amount should be in use at any one time. Radon should be used instead of radium when this is possible without loss of therapeutic efficiency. Patients should not remain under treatment by radium during an air raid unless in a basement or ground floor room strengthened up to the approved standard for an air raid shelter.

Radium should not be transported through the medium of the post office. It should be sent either by a special messenger or by a passenger train, in which case it should be handed to the guard and taken over from him at the station of destination. If less than 10 mg. is so conveyed, it should be enclosed in a container lined with 3 mm. of lead. For 10 to 50 mg. the container should be supported in the center of a box of a minimum of 1 foot in every dimension.

In the event of dispersal of radium—actual or suspected—the occurrence should be notified to the health officer, who will arrange for the danger area to be cordoned off immediately after fire and casualties, if any, have been dealt with. The occurrence should then be notified to the minister of health, who will arrange for experts to examine the site and advise as to further action.

Improving Health in the Army

Recent developments in the work of the army medical corps at home and abroad include a new type of convalescent depot. Situated in healthful surroundings and often near the sea, these depots have their own kitchen gardens and fowl yards and facilities for dancing and games. Massage and electrical treatment are available. Another institution is the army physical development center, which is designed to make the most of men who in the ordinary course would have been rejected because of slight physical disabilities. The object is to raise men just below category A to that standard by means of physical treatment. It is held that this can be done in 75 per cent of the cases. Another important branch of the work of the corps is the training of doctors in military duties, such as assessment of fitness, medical inspection, military sanitation (including improvised sanitation in the field) and cooperation in physical training. The newly commissioned medical officer first goes to a three months course at a depot and afterward to the Army School of Hygiene. There is a course on chemical warfare and another on tropical diseases.

Air Raid Casualties in October

As reported in previous letters, the civilian casualties from air raids when the indiscriminate bombing of our cities was at its height ran into thousands killed. With the great falling off of such attacks our casualties have become much fewer. The latest monthly figures show that 262 persons were killed in October and 361 wounded to the extent of being detained in hospitals. The casualties are classified as:

	Men	Women	Under 16
Killed or missing.....	136	92	34
Injured	186	129	46

BUENOS AIRES

(From Our Regular Correspondent)

Nov. 15, 1941.

The Prevalence of Venereal Disease

The Chilean minister of health, Dr. Salvador Allende G., recently published an extensive report on "Realidad Médico-Social Chilena." It reveals among other things that during the year 1938 more than twelve thousand women were registered as prostitutes. Of four thousand three hundred prostitutes who were examined monthly two thousand (64.4 per cent) were found to be either diseased or capable of transmitting disease. In Santiago de Chile alone three thousand prostitutes were registered. In more than two thirds of the cases social distress was the cause of the prostitution. A considerable number became prostitutes before they had completed their sixteenth year.

The decrease in syphilis in Argentina has been reported before. A new examination by Dr. D. A. Tello reveals that since the issuance of the law for the crusade against venereal disease (1937) the percentage of treated cases of syphilis has considerably decreased in the city of Cordoba, that is, from 0.17 in 1938 and 0.25 in 1939 it decreased to 0.0134 during the first five months of the year 1940. This reduction is ascribed to several causes: better possibilities for treatment, internment of the prostitutes until they are completely cured and better collaboration of the police.

On the other hand, it has been reported (H. Maciel, *Folha méd.*, Jan. 5, 1941) that in the Brazilian navy syphilis has increased in an alarming manner; according to the statistics of the Instituto Naval de Biologia for the years 1936, 1937 and 1938 an average incidence of 56.95 per cent of syphilitic infections must be expected among the members of the naval forces.

Results of the Second Latin American Congress for Criminology

At the second Latin American Congress for Criminology, which was held in Santiago during the first part of 1941, a number of resolutions were adopted. It was recommended that knowledge of the blood groups be generally disseminated for medicolegal purposes. Without definitely asserting the advisability of a classification of mental diseases, it was considered necessary to abolish differences in terminology employed by jurists and psychiatrists to improve mutual understanding. Moreover, terms which are no longer applicable in psychiatry are to be removed from legal compendiums. Constitutional perverts are to be subjected to protective measures. In the present state of biologic knowledge it is not possible to adopt eugenic measures that aim at a possible removal of criminal descendants. The conclusions of psychoanalysis are of unquestionable worth and should be taken into consideration in modern systems studying the suppression and prophylaxis of crime. Physical and mental hygiene of the inmates of prisons is to be considered, and suitable facilities and institutes are recommended for this purpose.

Campaign Against Cancer in Chile

A recent publication of N. Romero O. surveys the history of the campaign against cancer in Chile. After Dr. Lucas Sierra, together with his students Moya Camus, Montero Rodriguez, Mardones Acosta and Moenckeberg, at the beginning of this century, had begun disseminating current knowledge of cancer, a cancer institute was founded by Dr. Max Westhoeff in 1911 at the medical school of Santiago. In 1923 Romero began the campaign against cancer. During the same year radium became available and in 1930 the Instituto Nacional del Radium was officially opened. Its first director was Dr. Pardo Correa; on his death in 1933 he was succeeded by the present director, Dr. Leonardo Guzmán. The institute has eighty-five

beds, sixty-five of which are for women and twenty for men; twenty-five are for incurable patients. The institute has 1.5 mg. of radium and is equipped with x-ray apparatus. In addition to diagnosing and treating cancer patients, it gives postgraduate courses and organizes "cancer weeks." In 1937 the Comité Central Permanente del Cáncer was founded, which has branches in the most important cities; in 1940 the Liga Nacional del Cáncer was organized under the direction of Dr. Guzmán.

Gonorrheal Conjunctivitis

The Argentine ophthalmologist Dr. R. Laje Weskamp made the following observation on gonorrheal conjunctivitis: In the fourth division of the Argentine army, which includes some northern and western provinces (five thousand men) only 2 cases were observed in five years and both of them were unilateral. In an ophthalmologic clinic which treated 7,500 new patients from 1934 to 1940, only a single case was observed. On the other hand, a survey in 1937 disclosed 6,800 blind persons among thirteen million inhabitants. According to a census of the national institute for the blind, gonorrheal conjunctivitis is responsible for one third of the cases of blindness.

The Number of Physicians in Latin America

According to an announcement in the *Boletín de la Oficina Sanitaria Panamericana* the number of physicians in the different Latin American countries is as follows: Argentina 11,900, Bolivia 1,058, Brazil 25,000, Chile 2,061, Colombia 1,000, Costa Rica 170, Cuba 3,100, Dominican Republic 350, Ecuador between 500 and 600, El Salvador 200, Guatemala 500, Haiti 252, Honduras 130, Mexico between 13,000 and 15,000, Nicaragua 240, Panama 175, Paraguay 150, Peru 1,200, Puerto Rico 325, Uruguay 1,500 and Venezuela 1,200. The numbers for Brazil and Mexico probably include a number of not regularly trained and approved practitioners.

Regulation of Official Sale of Quinine in Argentina

In Argentina large quantities of quinine and other substances for the prophylaxis and treatment of malaria are dispensed free of charge or at very low prices. In order to prevent profiteering by reselling, special regulations have been issued which forbid and are intended to prevent resale except with a special permit of the Departamento Nacional de Higiene. The colors white and red have been reserved for this officially controlled quinine; that is, quinine which is retailed privately to the public cannot have these colors regardless of whether it is imported or domestically produced.

Marriages

JOSEPH PAGE POLLARD, lieutenant (j. g.) M. C., U. S. Navy, Tappahannock, Va., to Miss Mary Ruth Walker of Burlington, N. C., at Pensacola, Fla., Nov. 28, 1941.

MARION A. KING, Northampton, Mass., to Mr. Arthur C. Moulton of West Newfield, Maine, Oct. 4, 1941.

O. W. JOHNSON, Michigan City, Ind., to Miss Dorothy Herbert of Pottawattomie Park, Nov. 20, 1941.

ALEXANDER W. TERRELL JR., Dallas, Texas, to Miss Jeanne C. Braniff of Oklahoma City, Dec. 6, 1941.

PAUL NICKERSON, Sylacauga, Ala., to Mrs. Rachel Johns Nickerson at Siluria in November 1941.

HOWARD W. BEAVER, Rensselaer, Ind., to Miss Anna Louise Lorenz of Indianapolis, Oct. 19, 1941.

JULES I. KLFIN, Morgantown, W. Va., to Miss Henriette Liepold of Cincinnati, June 24, 1941.

FORD S. WILLIAMS, New Orleans, to Miss Anne Ella Fugate in Hazlehurst, Miss., Nov. 8, 1941.

WILLIAM JAMES COLLINS, Washington, D. C., to Miss Catherine C. Doran, May 30, 1941.

EDWARD J. DIEROLF, Crown Point, Ind., to Miss Geneva M. Nelson of Gary, Nov. 8, 1941.

Deaths

William Dick Cutter * Chicago, aged 63, Secretary of the Council on Medical Education and Hospitals of the American Medical Association since 1931, died at the home of his daughter in Johnson City, Tenn., January 22. Dr. Cutter was born in Brooklyn, Sept. 14, 1878. He received his A.B. degree from Yale University in 1899 and his M.D. degree from Johns Hopkins University School of Medicine in 1905. During the year 1900 he did graduate study in Berne, Switzerland. From 1899 to 1901 he was assistant in physiologic chemistry in Columbia University College of Physicians and Surgeons; from 1905 to 1906, resident physician and surgeon in the French Hospital in New York City. The following years were spent as a member of the hospital staff of the Copper Queen Consolidated Mining Company in Bisbee, Ariz. Thereafter Dr. Cutter concerned

himself wholly with medical education, becoming professor of physiology and pharmacology in the University of Georgia School of Medicine, 1911 to 1919; secretary of the State Board of Medical Examiners of New York from 1919 to 1923; dean of the New York Post-Graduate Medical School, 1923 to 1928, and dean of the School of Medicine of the University of Southern California from 1928 to 1931. Since 1931 he had devoted himself wholly to the work of the Council on Medical Education and Hospitals, in which position he earned the friendship and respect of leaders in medicine, and particularly in the

WILLIAM D. CUTTER, M.D.,
1878-1942

field of medical education, throughout the country. Under his leadership the annual Congress on Medical Education and Licensure assumed increasing significance. Before the attack of coronary thrombosis from which he died he had been intensively engaged in problems concerned with the maintenance of high standards of medical education under the conditions of the national emergency. Dr. Cutter was a fellow of the American College of Physicians and a member of the American Association for the Advancement of Science. For his scholarship he was awarded membership in Phi Beta Kappa and Sigma Xi. His contributions to medical literature were concerned primarily with problems of medical education. Since 1933 he had served also as manager-editor of the *Federation Bulletin* of the State Medical Boards. In his position in the headquarters office of the American Medical Association, which he occupied for eleven years, he carried great responsibility and manifested leadership.

Charles Davison * Chicago; Chicago Medical College, 1883; an Affiliate Fellow of the American Medical Association; professor of surgical anatomy, 1899-1900, adjunct professor of surgery from 1900 to 1905, professor of surgery from 1905 to 1917, professor and head of the department of surgery from 1917 to 1925 and since 1926 emeritus professor at the University of Illinois College of Medicine; assistant surgeon, Illinois Charitable Eye and Ear Infirmary from 1887 to 1892; served as attending surgeon at various times at the Cook County Hospital, president of the medical staff from 1917 to 1919 and chief of the department of surgery, 1919-1920; founder and formerly attending surgeon, West Side Hospital; surgeon in chief, University Hospital, from 1907 to 1942; surgeon, Research and Educational Hospital, 1925-1926; consulting surgeon, Illinois Masonic Hospital; one of the founders and fellow of the American College of Surgeons; fellow of the Founder's Group American Board of Surgery; president of the Chicago Surgical Society 1912-1913; trustee of the University of Illinois from 1905 to 1911; author of "Autoplastic Bone Surgery," 1916; aged 84; died, January 19, of cerebral hemorrhage.

Eugene Sterling Kilgore * San Francisco; Harvard Medical School, Boston, 1909; member of the House of Delegates of the American Medical Association in 1920, secretary of the Section on Practice of Medicine from 1922 to 1925 and chairman 1925-1926; assistant in medicine at the University of California Medical School from 1912 to 1914, instructor from 1914 to 1916, assistant professor from 1916 to 1925, associate clinical professor from 1925 to 1930 and since 1930 clinical professor; member of the Association of American Physicians; served during the World War; was consultant in cardiovascular diseases for the U. S. Veterans Bureau for many years; on the consultant staffs of the French Hospital and the Chinese Hospital; chief of medical department, St. Joseph's Hospital; aged 63; died, January 2, of coronary thrombosis.

Broadstreet Henry Mason * West Hartford, Conn.; Medical School of Maine, Portland, 1907; member of the New England Society of Psychiatry; past president of the Connecticut Hospital Association; instructor in psychiatry at the University of Michigan Medical School, Ann Arbor, from 1921 to 1923 and assistant director of the Psychopathic Hospital during the same period; neuropsychiatrist to the United States Veterans Bureau; assistant superintendent from 1914 to 1918 of the Worcester (Mass.) State Hospital and acting superintendent from 1918 to 1921; first assistant superintendent of the Peter Bent Brigham Hospital, Boston, from 1923 to 1927; superintendent of the Waterbury (Conn.) Hospital from 1927 to 1941; aged 60; died, January 1, of heart disease.

George de Tarnowsky * Chicago; Northwestern University Medical School, Chicago, 1900; professor of surgery at the University of Illinois College of Medicine; formerly clinical professor of surgery at the Loyola University School of Medicine; past president of the Chicago Gynecological Society; president of the Chicago Surgical Society, 1938-1939; served as a colonel in command of the 378th regiment during the World War; was awarded the Distinguished Service Medal and was an Officer of the Legion of Honor of France; attending physician, Cook County Hospital, from 1913 to 1920; author of "Surgery of the Zone of the Advance" and "Emergency Surgery"; aged 68; on the staff of the Ravenswood Hospital, where he died, January 20, of cerebral hemorrhage.

William Lamar Bryan Jr. * Columbia, S. C.; Vanderbilt University School of Medicine, Nashville, Tenn., 1939; at one time assistant in the department of anatomy at his alma mater; from July 1940 through June 1941 served on the faculty of Tulane University of Louisiana School of Medicine, New Orleans as instructor in the department of neuropsychiatry; since July 1941 served as professor of hygiene and assisted his wife as university physician at the University of South Carolina; aged 27; died, Dec. 10, 1941, in the Providence Hospital of renal failure.

Anthony Parisi, Newark, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1918; member of the Medical Society of New Jersey; fellow of the American College of Surgeons; attending surgeon, St. Michael's Hospital and Columbus Hospital; assistant surgeon, Newark City Hospital; consulting anesthetist, Hospital of St. Barnabas and for Women and Children; aged 48; died, Dec. 18, 1941, of coronary occlusion.

Joseph Brettauer * New York; Karl-Franzens-Universität Medizinische Fakultät, Graz, Austria, 1887; member and in 1928 president of the American Gynecological Society; fellow of the American College of Surgeons; consulting gynecologist, Mount Sinai Hospital, New York; United Hospital, Port Chester, N. Y., and the New Jersey State Hospital, Greystone; aged 78; died, Dec. 26, 1941, of coronary artery disease.

Thomas William Plant * Chicago; Bennett Medical College, Chicago, 1916; fellow of the American College of Surgeons; for many years on the staff of St. Mary of Nazareth Hospital; aged 54; died, Dec. 29, 1941, of injuries received in an automobile accident.

Wilson R. Scott, Dayton, Ohio; Chicago Physio-Medical College, 1898; aged 75; died, Dec. 7, 1941, in the Miami Valley Hospital of coronary thrombosis.

KILLED IN ACTION

Samuel Earle Johnson * Medical Inspector, Commander, United States Navy; Vanderbilt University School of Medicine, Nashville, Tenn., 1911; entered the regular navy Dec. 27, 1920; aged 52; was killed during the Japanese raid on Pearl Harbor, Dec. 7, 1941.

Bureau of Investigation

VARIOUS "CURES" BANNED FROM THE MAILS

Abstracts of Some U. S. Post Office Fraud Orders

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of *THE JOURNAL*. Following are brief abstracts of some fraud orders not dealt with previously.

Bumpass Medicine Co.—This concern, also known as Bumpass Medicine Co., was conducted at Corinth, Miss., by a Mrs. Ethel Bumpass. Through the mails she represented that her "Bumpass Asthma Treatment" would overcome asthma, that "Bumpass T. B. Remedy" would cure tuberculosis and that "Bumpass Body Builder Tonic" would correct rundown, debilitated and underweight conditions. Of course, she employed the usual testimonials. Government chemists reported that the tuberculosis nostrum was essentially a water-alcohol suspension containing pine tar and invert sugar, in an acidic, viscous, cloudy brown liquid containing a small amount of ground plant material, that the asthma mixture was chiefly an acidic water-alcohol solution containing a reducing sugar and tannin from plant extracts, and that the "body builder" contained the same ingredients plus an alkaloidal material. As it was found that Mrs. Bumpass was not a physician, chemist or pharmacist and employed no one possessing these qualifications, and as expert medical testimony showed that her nostrums would not produce the implied results, a fraud order was issued against the business on Oct. 29, 1940.

Purviance Sanitarium.—This outfit at Lincoln, Neb., was run by a Walter Charles Purviance, M.D., who is not a member of the American Medical Association. The records indicate that he has advertised in news papers and that he was actively connected with John R. Brinkley (with whose record readers of *THE JOURNAL* are quite familiar) when the latter was running his outfit at Milford, Kan. It is not surprising that, like some other associates of Brinkley in his "gland cure" promotion, Purviance later went into the business on his own and advertised as a "prostate specialist." The Post Office investigation revealed that he sent out a form letter in which he boasted, "For many years I have been performing the 'Compound Operation.'" (The latter was Brinkley's stock in trade.) But if one had prostate trouble and was unable to go to the Purviance Sanitarium, he could treat himself at home with Purviance's "P. R. Tablets." Further, he was told that that nostrum was "not a patent medicine" but "a private prescription," and "the chief ingredient has remarkable curative properties which have been thoroughly demonstrated by laboratory experiments, and by administration to men over a period of thirty years." Besides it "reduces enlarged prostates," "tones up the bladder" and "restores lost manhood." What "pep" nostrum vender could offer more? And what was this "remarkable" remedy? Government chemists reported that each $\frac{1}{2}$ grain (0.3 Gm.) tablet contained about 4 grains (0.26 Gm.) of chromium sulfate. Expert medical testimony was introduced which showed that chromium sulfate is not recognized as having any valuable effect in treating prostatic or any other disorder, that it is only slightly absorbed by the body and that absorption of chromic acid by the system in any considerable degree would produce poisonous effects rather than benefit. As the business was shown to be a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, a fraud order was issued against W. C. Purviance and the Purviance Sanitarium on Jan. 19, 1940.

Rose Dorf's Cosmetics.—Two products, "Skin Life" and "Dorf's Beauty Lotion," were promoted through the mails by a Rose Dorf of New York, operating variously as "Mme. Cecelia" and "Mme. Rose Dorf," who previously had engaged in the millinery business and had no medical training. When first cited by the Post Office Department, she admitted that she knew nothing about cosmetics or their "dangers and liabilities" and added that because of dwindling receipts she was abandoning her enterprise. As no evidence developed to show that she had done so, the Post Office again took up the case and produced expert medical testimony regarding the composition of her preparations and the falsity of the claims made for them. It was shown that "Skin Life" consisted essentially of ammoniated mercury in a base of hydrous wool fat and possibly some wax and that not only would it be useless for ridding the face of pimples, liver spots and wrinkles, as it was represented to do, but the ammoniated mercury that it contained would make it dangerous to use. It was further shown that "Rose Beauty Lotion" was chiefly salicylic acid and could effect no more than a superficial peeling of the skin, without removing the underlying factors responsible for pimples, blackheads, oily skin and other conditions for which it was advertised. A fraud order was issued against the names of Mme. Rose Dorf and Mme. Cecelia on April 21, 1941.

T. M. Laboratories.—This Chicago concern, also known as Tobaccoline Sales Division, was run by a W. K. Miller and a J. P. Thomas, who operated from a post office box and sold "Tobaccoline" by mail as a cure for the tobacco habit. Their advertising decryd the use of any competing product and declared that "Tobaccoline is not a patent medicine." Obviously it was nothing else. Government chemists reported it to consist of capsules each containing $\frac{1}{2}$ grain (0.008 Gm.) lobeline sulfate with milk sugar. Expert medical testimony was introduced to show that since the effects of lobeline are the same as or similar to those of nicotine, this nostrum did not and could not afford a "safe," "sure" and "harmless" means of ending the tobacco habit, which cannot be accomplished without the patient's will power. In fact, the expert medical witness testified that a large number of persons whom he had treated with lobeline had returned to the tobacco habit. The fraud order was issued against this scheme on Jan. 30, 1941.

KENNY METHOD OF TREATMENT OF INFANTILE PARALYSIS

To the Editor:—In view of the wide publicity given the Kenny method of treatment of acute poliomyelitis, a copy of the treatment given in the 1906 edition of Osler's *Practice of Medicine* (p. 917), which I enclose, may prove of interest.

The treatment of acute infantile paralysis has a bright and a dark side. In a case of any extent complete recovery cannot be expected; on the other hand, it is remarkable how much improvement may finally take place in a limb which is at first completely flaccid and helpless. The following treatment may be pursued. If seen in the febrile stage, a brisk laxative and a fever mixture may be given. The child should be in bed and the affected limb or limbs wrapped in cotton. As in the great majority of cases the damage is already done when the physician is called and the disease makes no further progress, the application of blisters and other forms of counterirritation to the back is irrational and only cruel to the child.

The general nutrition should be carefully maintained by feeding the child well, and taking it out of doors every day. As soon as the child can bear friction the affected part should be carefully rubbed, at first once a day, subsequently morning and evening. Any intelligent mother can be taught systematically to rub, knead and pinch the muscles, using either the bare hand or, better still, sweet oil or cod liver oil. This is worth all the other measures advised in the disease and should be systematically practiced for months or even, if necessary, a year or more. Electricity has a much more limited use and cannot be compared with massage in maintaining the nutrition of the muscles. The faradic current should be applied to those muscles which respond. The essence of the treatment is in maintaining the nutrition of the muscles, so that in the gradual improvement which takes place in parts, at least, of the affected segments of the cord the motor impulses may have to deal with well nourished, not atrophied, muscle fibers.

If my memory serves me, the immobilization of patients with acute poliomyelitis first came into vogue in this country with the 1916 epidemic.

SIDNEY V. HAAS, M.D., New York.

STETHOSCOPIC RECORDS OF HEART SOUNDS

To the Editor:—In a communication to *THE JOURNAL* of Dec. 20, 1941, Col. J. E. Ash, curator of the Army Medical Museum, Washington, D. C., refers to my stethoscopic records of heart sounds, murmurs and arrhythmias and states that there are "on file at the Army Medical Museum records . . . prepared . . . in 1939."

Quite a number of men in this and other countries have made recordings of heart sounds, and from the standpoint of priority no claim is made. An article in the *American Journal of the Medical Sciences* of November 1941 clearly sets forth this point of view.

The only claims that I make for this series of records are (1) their "high fidelity," (2) completeness, (3) a short explanation of what is to be heard before the illustration, (4) availability to any one at a reasonable price, (5) satisfactory reproduction even with a cheap radio-phonograph in a living room and (6) the fact that they are listened to with one's own stethoscope and that, if directions are followed, one hears the illustrations with the same intensity and quality of sound as was heard with the stethoscope on the patient's chest when the recording was made.

I am sorry that Colonel Ash stated "I understand Dr. Geckeler knew of these records." I had never heard of them.

GEORGE D. GECKELER, M.D., Philadelphia

Kansas December Report

The Kansas State Board of Medical Registration and Examination reports the written examination for medical licensure held at Topeka, Dec 9-10, 1941 The examination included 10 questions An average of 75 per cent was required to pass Three candidates were examined, all of whom passed One physician was licensed to practice medicine by reciprocity and 1 physician so licensed on endorsement of credentials of the National Board of Medical Examiners The following schools were represented

School	PASSED	Year Grad	Number Passed
College of Medical Evangelists		(1938)	1
University of Chicago The School of Medicine		(1941)	1
University of Minnesota Medical School		(1941)	1

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Harvard Medical School		(1934)	Missouri

School	LICENSED BY ENDORSEMENT	Year Grad	
Tufts College Medical School		(1926)	

District of Columbia Reciprocity Report

The District of Columbia Commission on Licensure reports 6 physicians licensed to practice medicine by reciprocity on Dec 9, 1941 The following schools were represented

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Georgetown University School of Medicine		(1937)	Penn.,
Johns Hopkins University School of Medicine		(1938)	Maryland
University of Maryland School of Medicine and College of Physicians and Surgeons		(1913), (1925)	Maryland
New York University College of Medicine		(1915)	New York
Western Reserve University School of Medicine		(1911)	Ohio

New Mexico Endorsement Report

The New Mexico Board of Medical Examiners reports 8 physicians licensed to practice medicine by endorsement on Oct 13-14, 1941 The following schools were represented

School	LICENSED BY ENDORSEMENT	Year Grad	Endorsement of
University of Colorado School of Medicine		(1937)	Calif.,
Loyola University School of Medicine		(1941)	Calif.,
Northwestern University Medical School		(1931)	Calif.,

University of Oklahoma School of Medicine		(1911)	Oklahoma
Universidad Central de Espana		(1911)	Spain

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Alleged Failure to Administer Tetanus Antitoxin.—Mrs. Ernest Hembree, through the negligent operation of an automobile by Owen Hembree, sustained "severe cuts and bruises about the legs, and broken bones at the point of the cuts." She was taken immediately to the Von Keller Hospital and attended by Dr. Von Keller. Five days latter her husband removed her to another hospital and placed her under the care of Dr. Irby. At that time, according to Dr. Irby, the patient had a high fever, was nervous, had severe headaches and was suffering extreme pain about the injuries on her legs, the symptoms indicating to Dr. Irby the onset of tetanus, but whether or not he administered tetanus antitoxin at that time is not clear. In accordance with his directions the patient that day or the next was taken to a hospital in Oklahoma City and placed under the care of Dr. O'Donoghue, who immediately administered antitetanus serum. The next day the patient complained of stiffness in her neck and tightness around her jaws, and more tetanus antitoxin was administered. Ten days after the accident the patient died of tetanus infection. The husband then brought suit against Owen Hembree and against Dr. Von Keller and the Von Keller Hospital, the case against the physician and the hospital being based on their alleged failure to administer tetanus antitoxin to the patient. Judgment was rendered against Owen Hembree but the trial court directed a verdict in favor of the physician and the hospital, and the plaintiff appealed to the Supreme Court of Oklahoma.

The plaintiff sought to have the doctrine of *res ipsa loquitur* applied to the case, that is, the plaintiff argued that the facts and circumstances surrounding the medical treatment of the patient were wholly within the knowledge of the defendants and the fact of death from tetanus speaks for itself, raising a presumption of negligence on the part of the defendants, thus establishing a *prima facie* case and shifting the burden of proof to them. The Supreme Court of Oklahoma, however, refused to apply the doctrine, quoting with approval the following language in *Ewing v. Goode*, 78 F. 442:

Before the plaintiff can recover, she must show by affirmative evidence: First, that defendant was unskilful or negligent; and, second, that his want of skill or care caused injury to the plaintiff. If either element is lacking in her proof, she has presented no case for the consideration of the jury. The naked facts that defendant performed operations upon her eye, and that pain followed, and that subsequently the eye was in such a bad condition that it had to be extracted, established neither the neglect and unskilfulness of the treatment, nor the causal connection between it and the unfortunate event. A physician is not a warrantor of cures. If the maxim, "*Res ipsa loquitur*," were applicable to a case like this, and a failure to cure were held to be evidence, however slight, of negligence on the part of the physician or surgeon, causing the bad result, few would be courageous enough to practice the healing art, for they would have to assume financial liability for nearly all the "ills that flesh is heir to."

The Court accordingly held that the fact that the patient died from tetanus did not raise a presumption of negligence on the part of the defendants thus to establish a *prima facie* case and shift the burden of proof to the defendants.

The plaintiff apparently contended that a failure to administer tetanus antitoxin under the circumstances was improper practice. To prove that the defendant physician and the hospital had not, contrary to their claim that they had, administered tetanus antitoxin, he relied on circumstantial evidence which he alleged established the following facts: Tetanus developed and the patient died as a result thereof in the average period in such cases in which antitoxin is not administered; if antitoxin is administered, tetanus is absolutely prevented in 95 per cent to 100 per cent of cases of similar injury; if tetanus does develop

after antitoxin is administered, the period prior to the development of the disease is doubled or longer and the attack is much milder than when the antitoxin is not administered; the patient had unmistakable symptoms of the disease two or three days prior to her death and numerous injections of antitoxin were administered thereafter. One witness who had accompanied the patient when she was taken to the Von Keller Hospital immediately following the accident testified that the hypodermic which Dr. Von Keller had testified he called for and administered was a hypodermic of morphine and not of antitetanus serum; there was no showing on the patient's chart that antitetanus serum had been administered; there was no charge shown for the antitoxin in the statement of account presented by Dr. Von Keller to the plaintiff, and it is customary to make such charge and customary that some memorandum thereof be given by the nurse to the bookkeeper so that the latter can make the proper charge.

Assuming, said the Supreme Court, though we do not now decide, that the failure to use the antitoxin was improper practice, we look first to the evidence on the issue whether the defendants actually administered antitoxin to the patient. The defendants introduced ample evidence to prove that the serum was administered in proper time, while the plaintiff relies on the records in the hospital, the reaction of the patient and the testimony of the witness who accompanied the patient into the hospital immediately after the accident as circumstantial evidence that the serum was not used. The witness who had accompanied the patient into the hospital immediately following the accident seemed to have owned or to have worked in a drug store and on the basis of such a background she testified that she knew that the hypodermic that she saw prepared for the patient was one of morphine and not of tetanus antitoxin. She stated that she saw no other hypodermic administered to the patient. This witness's testimony, said the Court, is of no probative value. She did not attend the patient constantly after the patient's entry in the hospital and she was in no position to observe all that was done by the physicians and nurses. There was other evidence that the defendant physician had administered morphine. The mere fact that the witness saw the hypodermic prepared and given was no indication that antitetanus serum was not administered also. The Court then went on to consider the testimony of medical witnesses concerning the patient's condition and her reactions as indicative of a lack of tetanus antitoxin. Dr. Irby, after testifying as to the patient's condition when he examined her after her removal from the defendant hospital, testified that antitetanus serum was generally considered as 100 per cent preventive; that he had never heard of a case in which antitetanus serum was administered in which tetanus later developed, and that the incubation period from the date of the injury to the date of the symptoms was six to ten days. On cross examination Dr. Irby said that his statement concerning the period of incubation and percentage of cures was based wholly on his reading and hearing lectures on the subject, that he had never treated a patient with tetanus but had administered the antitoxin as a preventive to 200 or 300 patients. Dr. O'Donoghue stated that the incubation period of tetanus would ordinarily be six to ten days but that the period could be shorter or much longer. According to Dr. O'Donoghue's testimony, antitetanus serum is efficient in the prevention or delay of tetanus but is not an absolute preventive. He knew of 2 patients who, after the administration of tetanus antitoxin, had within the ordinary incubation period developed tetanus and died therefrom. He was of the opinion that while the administration of antitetanus serum would ordinarily increase the incubation period, this would not necessarily be true in every instance. The plaintiff also called as a witness Dr. Baxter, who testified that while the serum was regarded as a preventive he doubted whether it was 100 per cent efficient. The period of incubation, he stated, was "eight to ten days, to six weeks or three months," and the development of tetanus might be an indication that the serum was not given. He qualified the latter statement, how-

ever, by testimony to the general effect that the patient could have received the serum and yet have developed tetanus. In our opinion, said the Court, the evidence on this point which we have discussed is not sufficient to remove the issue from the realm of conjecture and speculation. We find that among the cases in which the antitoxin is duly administered the patient may develop tetanus within from three days to several weeks. Judging from the evidence, physicians and medical instructors are yet uncertain concerning the efficiency of the serum. It is highly efficient and is recommended as a preventive, but it is not infallible. The condition of the patient and the nature of his wounds play a large part in the result. Some react favorably sooner than others. No one could say, without indulging in mere speculation and conjecture, that tetanus would not have occurred in a particular case had the serum been administered at the proper time.

As further indicative of the alleged fact that the defendants had not administered tetanus antitoxin, the plaintiff pointed to the failure of the hospital record or chart of the patient to show that the antitoxin was administered and to the absence of a charge therefor made separately on the statement account presented to the plaintiff by the defendant. Dr. O'Donoghue, testifying for the plaintiff, stated that hospital charts are supposed to contain a list of all medicines and treatments of every kind that are administered to the patient, that if the patient receives an injection of antitetanus serum the hospital records should contain a reference thereto and that the failure to show such injection would be some evidence that none was given. Dr. O'Donoghue, however, further testified that errors often appeared in hospital records and that such omissions occur sometimes when emergency treatment is being administered to a patient and also when the attending physician fails to notify the nurse of the treatment. Dr. Baxter testified that the hospital record of the patient in this case purported to be for the period from 3:30 a. m., when the patient was admitted, to 7 a. m. of the same day. The record showed that the patient was admitted to the x-ray room, where films were made, and was then carried to the operating room. The record indicated that there had been an injection of morphine and atropine made in the x-ray room, but the record itself showed nothing of what transpired in the operating room. The evidence referred to, said the Court, does not establish sufficient facts on which to base a reasonable inference that the antitetanus serum was not administered. The operating room was the proper place in which to administer the serum, yet there was absolutely no record of what transpired there throughout the entire period during which the patient was in that room. In this case it is shown without contradiction that the records were not correctly kept. The Court accordingly concluded that the hospital chart afforded no basis on which it could be concluded that antitetanus serum had not been given.

The action of the trial court in directing a verdict in favor of the hospital and of Dr. Von Keller was accordingly affirmed. —*Hembree v. Von Keller*, 119 P. (2d) 74 (Okla., 1941).

Optometry Practice Acts: Right of a Corporation to Employ Licensed Optometrists.—Since prior to 1915 the defendant, Kindy Optical Company, had pursued its corporate activities in the state of Wisconsin. In doing so it employed two licensed optometrists to whom it furnished certain devices and machines used for testing vision, and their prescriptions for glasses were filled in the defendant's store. In 1915 the Wisconsin legislature enacted a statute regulating the practice of optometry.

The act of 1915 provided that "the furnishing, using or employment of any means, device or machine, designed or calculated to aid any person in the selection or fitting of spectacles or eyeglasses . . . shall constitute the practice of optometry." It also regulated the conduct of "every person, firm or corporation, engaging in the practice of optometry"

and fixed penalties against both employers and employees in case of noncompliance with the law. After the enactment of this law, the defendant continued to pursue its activities without change. In 1938 the Milwaukee Optometric Society petitioned the court for an order to oust the defendant from the practice of optometry. From a judgment enjoining the defendant and its employees from so practicing, the defendant appealed to the Supreme Court of Wisconsin.

The plaintiff contended that a corporation may not practice a profession by employing licensed operators. But, said the Supreme Court, optometry is readily distinguished from a profession in the practice of which diseases of the eye are treated. It is a mechanical art requiring skill and knowledge of the use of instruments designed to measure and record the errors and deviations from the normal found in the human eye. Although certain standards of education are prescribed by the optometry practice act, optometry is not a part of the practice of medicine. The Wisconsin legislature, in the opinion of the Court, dealt with optometry as a skilled calling, not as a profession involving a relation of special confidence between practitioner and patient. The legislature did not attempt to classify optometry so as to prevent the engagement of optometrists by any one to assist in a business in which such a calling is naturally an accompanying factor.

The Court was not impressed with the emphasis that the respondent placed on the fact that the words "unprofessional conduct" were used in the optometry practice act. Phrases work themselves into statutes and literature on a subject because they become convenient in the meeting of situations requiring description, the Court observed, but they cannot be considered of such strength or importance as to carry a meaning contrary to the general import of the statute. A duly registered and licensed optometrist who does not comply with the law, the Court pointed out, would properly enough lose his license, and the phrase in question does not go beyond that. Furthermore, the statute provides for the discipline of an employer when there is a failure to comply with it. It is provided that when an employer violates any of the provisions of the chapter regulating optometry an optometrist cannot remain in his employ and retain his license.

Since the legislature sought to regulate the employment of optometrists, the Court pointed out, it must have intended that there be such employment.

The purpose of the statute to insure competent service to the public, the Court thought, may be fully accomplished although the optometrist rendering the service is an employee of a corporation. The long continued practice of corporations in employing licensed optometrists to test the eyes of customers, concluded the Court, is not a violation of the law regulating the practice of optometry. The judgment of the lower court was reversed and the cause remanded with directions to dismiss the complaint.—*State ex rel. Harris v. Kindy Optical Co.*, 292 N. W. 283 (I'lls., 1940).

Society Proceedings

COMING MEETINGS

Annual Congress on Medical Education and Licensure, Chicago, Feb. 16-17.

American Orthopsychiatric Association, Detroit, Feb. 19-21. Dr. Norville C. LaMar, 149 East 73d St., New York, Secretary.

Central Surgical Association, Chicago, Feb. 27-28. Dr. George M. Curtis, Ohio State University, Columbus, Ohio, Secretary.

Mid South Post Graduate Medical Assembly, Memphis, Tenn., Feb. 16-13. Dr. Arthur F. Cooper, 165 Madison Ave., Memphis, Tenn., Secretary.

Pacific Coast Surgical Association, San Francisco and Del Norte, Calif., Feb. 17-20. Dr. F. L. Reider, Stanford University Hospital, San Francisco, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Association of Diverticulitis and Carcinoma of Colon. L. K. Stalker, E. T. Rulison and J. D. White, Rochester, N. Y.—p. 440.

Third Bile Fraction.—Rehfuss and Williams made chemical studies of the bile aspirated by duodenal drainage, and they found a definite difference in the physical appearance and the chemical characteristics of the third portion of the bile (liver fraction). The differences are in color, consistency, solubility and quantity of certain elements present. Duodenal drainage apparently does something more than clear the ductus; it removes a variable amount of bile which possesses chemical and possibly toxic properties. Duodenal intubation in selected cases may present another weapon in reducing certain abnormal non-protein fractions from the blood.

Toxicity Studies on Diethylstilbestrol.—Aaron and his co-workers determined the toxicity of diethylstilbestrol by giving 30 patients with chronic arthritis 1 to 3 mg. of the drug. At the onset of treatment all patients received a daily dose of 3 mg. This was reduced to 2 or to 1 mg. in 15 cases when untoward symptoms (nausea and postmenopausal bleeding) developed. Other symptoms were not prominent; occasionally the fact that a patient had had perspiration, headache, palpitation and urinary frequency could be elicited on inquiry but was seldom volunteered. On the contrary, 80 per cent of the patients voluntarily stated that their general feeling of well-being was much improved. None of the results of tests done before and after therapy indicate that a change in hepatic function was produced after five to nine weeks of treatment with diethylstilbestrol. There was an apparent but not significant decrease of bile in the plasma. There was a slight apparent increase in the total cholesterol, the increase being due to a rise in the ester fraction. There was no significant change in the blood count, the urinary content, blood urea and blood dextrose after diethylstilbestrol therapy.

Blood Loss in Obstetric Cases.—Conn and his co-workers determined the average blood loss of 2,000 mothers having vaginal deliveries. Eight hundred of the women were primigravidas, and 1,200 were multigravidas. The average blood loss for the primiparas was 388 cc., and for the multiparas it was 280 cc. The increase in the average blood loss corresponded to the increase in the mother's weight. A similar increase followed the delivery of a large baby or of twins. Furthermore, with an increase in the duration of labor and in the weight of the placenta the blood loss was usually increased. Of the 2,000 women, 66 per cent were delivered spontaneously with an average blood loss of 278 cc.; with low forceps delivery the average loss was 404 cc., and with midforceps delivery the average loss was further increased. Of the 800 primiparas, 170 had a blood loss of 600 cc. or more, as did 144 of the 1,200 multiparas. Close analysis reveals that the patients with a blood loss in excess of 600 cc. bore practically the same relation to the various factors which played a part in increasing the blood loss in the group as a whole. Of the 314 patients, the 126 with perineal wounds lost between 600 and 700 cc. of blood. This suggests that incision may not always be justified. In 60 patients, instrumental delivery was judged to be the cause of the increased loss of blood, in 56 there seemed to be no obvious reason for the excessive blood loss, in 41 the cause appeared to be uterine atony and in 32 sedatives played a part.

Significance of Heartburn.—Williams made a roentgen and fluoroscopic study of pregnant women with and without heartburn. As damage through repeated roentgen exposures was possible, observations were somewhat curtailed. Initially a 200 cc. barium sulfate meal was given and its propulsion followed through the esophagus, and its behavior in the stomach was watched. Evidence of hiatus hernia, esophageal dilatation, regurgitation and reverse peristalsis were observed whenever the patient suffered from heartburn. Observations left no doubt that in patients without heartburn the stomach suffered encroachment by the pregnancy. There were no visible pathologic alterations in 7 women with heartburn, in 3 there was moderate dilatation of the lower third of the esophagus, in 1 the passage of barium was delayed at the cardia because of slight regurgitation and in 1 a hiatus hernia, with a dilatation above it, was observed. These revelations imply that heartburn rarely rests on an anatomic basis but that its origin and development lie within the domain of pathologic physiology. Granting that heartburn is essentially a neuromuscular phenomenon it seemed to the author that prostigmine may be a rational therapeutic means of relieving the symptom. Accordingly, 16 patients with severe heartburn were given an injection of 1 cc. of prostig-

mine, 1:2,000, and after a single dose 1 patient was not benefited and 14 were made comfortable or were entirely relieved within twenty-four hours. In about half of them the distress gradually recurred in seven to ten days. A second dose proved as effective as the first. Repeated injections kept the patients free of the symptom with no untoward results. Dietary and other hygienic indiscretion may provoke heartburn. Sometimes alkalis afford relief, implying gastric hyperacidity. Chemical analysis, however, showed gastric hypoacidity more often, occasionally complete anacidity. Consequently hydrochloric acid has been effective in some instances. Whatever the benefits of alkali or acid therapy, not the composition of the gastric juice but temporary impairment of the neuromuscular mechanism, which controls the transportation of the gastric contents, is at fault.

Varicose Veins.—Brunstein believes that the disturbing sequels (pain, discomfort and disability) often encountered in the treatment of varicose veins may be prevented by the empty vein technic, which will really keep the patient ambulatory and able to pursue his usual activities. Sclerosis by injection into empty veins will cause blocking of the varices by fusion of the opposing surfaces of the vessel, and direct contact of the sclerosing solution with the intima irritates the endothelium; the irritation is followed by an ample production of fibroblasts. These are instrumental in firmly binding the opposing surfaces of the vessel. Furthermore, the results of injections into empty veins are cosmetically more gratifying, and discoloration is greatly reduced. The objection to the technic is the possibility of the sclerosing solution's escaping through communicating veins into the deep venous circulation, but this cannot be substantiated. The technical difficulty of injecting collapsed varicosities is the only real disadvantage of the method. Adequate compression is necessary to maintain large varicosities in a collapsed and well supported state after injection.

Methylene Blue.—Golden and Martin observed that the postoperative morbidity was reduced if patients were given food as soon as nausea and vomiting stopped. However, as cessation of vomiting and nausea need not always mean that the intestinal tract is absorbing and the kidneys are functioning they sought a physiologic basis for intestinal absorption and renal function. A dye seemed to be indicated, and they tried methylene blue. The dye, 0.065 Gm in a capsule, was given by mouth with as

much water as possible six to eighteen hours after operation. The patient was requested to void, or he was catheterized prior to its administration. During the next three hours, small amounts of water were given repeatedly, after which the patient was encouraged to void or he was catheterized at the end of five hours. If the urine obtained was greenish blue, it was assumed that the intestine was able to absorb and that the kidneys could secrete, and feeding by mouth was started. Failure to obtain a secretion of the dye in the urine should invariably suggest that the patient is sick and a faint color that oral feeding should be proceeded with slowly. Since the authors have used methylene blue as a physiologic test of the patient's ability to use food they have observed a definite reduction in wound infection, postoperative nausea and vomiting and they practically no longer have need for the Wangenstein appliance.

Preventing Cartilage Grafts from Warping.—New and Erich point out that finished grafts of fresh costal cartilage will not warp or become distorted if before use the cartilage is placed in a test tube containing water or aqueous sodium ethyl mercurithiosalicylate (merthiolate) and the tube is then placed upright in a beaker containing boiling water. Although the solution in the test tube will in time become hot it will not boil and cause multiple ruptures in the cartilaginous matrix. The solution in the test tube will remain 3 or 4 C. below the boiling point of water for the ten minutes that the water in the beaker is allowed to boil. Cartilage which has been subjected to such a heating process will undergo a certain amount of warping while it is cooling; therefore it is to be cut to the desired shape after it has cooled. Furthermore, if the end of a cartilaginous implant is trimmed to a feather edge, the extremely thin margin may be remedied by cutting away that portion of the fine edge that is bent. When the cartilage is removed from the test tube, it is immersed for fifteen minutes in cold sterile physiologic solution of sodium chloride. With a few exceptions, the defect of the face can be fully prepared for reception of the implant by the time the treated cartilage has been made available for proper shaping. None of the cartilage implants that the authors have made by their method has undergone any distortion postoperatively.

Tuberculosis in Schools.—Shields employed the Mantoux technic to find the positive reactors to the purified protein derivative of tuberculin among 4,320 Rhode Island students (14 less than 5 years of age; 264, 5 to 9; 909, 10 to 14; 2,900, 15 to 19, and 161 more than 20). The percentage of positive reactors for the whole group was 47.5, and for the different ages it was respectively 21.4, 22.3, 45.2, 50 and 68.9. Roentgenograms of the chest were made of all students giving a positive reaction. Students with roentgen evidence of the disease were notified to visit their family physician, who simultaneously received a detailed report of the observations. No consistent relation was observed between the percentage of positive reactors to tuberculin and the death rate from tuberculosis (464 per hundred thousand population). This experience casts some doubt on the often quoted dictum of Myers "that the tuberculosis

problem in a community is measured by the relative frequency of the tuberculin reactors." Among the 1,850 students who had roentgenograms of the chest made, 3 had the adult type of tuberculosis and roentgen evidence of a healed childhood lesion was found in 799. A healed primary lesion was diagnosed when calcified foci were observed in the pulmonary field.

Vitamin C for Mucous Membrane Tuberculosis.—Bogen and his associates determined the effect of vitamin C on the lesions of the mucous membranes of 196 patients with tuberculosis. The patients were divided, in rotation, into seven groups; the sanatorium diet of three groups was supplemented by vitamin C and of three by other dietary supplements, and one group was not given any special medication but was kept as a sort of psychologic control or check on the mental stimulation and the apparent improvement which so often result after any new treatment. Subjectively, as a result of treatment, the general condition of the patients receiving vitamin C was better than that of the other four groups of patients, although the status of the pulmonary condition did not support this impression. Despite the absence of significant objective improvement in the general condition, bronchoscopic or proctoscopic examination and clinical observation revealed improvement in the lesions of the mucous membranes in nearly 90 per cent of the patients receiving additional vitamin C, as compared to less than half of those in the other four groups. A similar beneficial effect was observed in patients with laryngeal tuberculosis; three fourths of those receiving vitamin C showed improvement, as compared to only half of those not receiving such treatment.

Roentgen Therapy for Bronchiectasis.—Carpenter and his associates used roentgen irradiation for the treatment of 38 patients with chronic bronchiectasis which had been observed and treated for months or years but had remained practically stationary. The physical factors of the therapy were 200 kilovolts, a distance of 50 cm. and filtration through 0.5 mm. of copper; the size of the field was 10 by 10 cm. for children or 10 by 15 cm. for adults; the average total dose for each anterior, lateral and posterior field varied from 1,200 to 1,700 roentgens, and the average daily dose varied from 100 to 200 roentgens, given through two fields. Treatment was usually completed in three weeks. No adverse reactions other than a few gastrointestinal upsets (attributable to "irradiation sickness") and occasional slight secondary anemia were encountered. During treatment and for several months after its completion cough and expectoration were usually increased, after which there was a gradual cessation of symptoms in the patients who responded to the therapy. The patients who experienced no improvement noticed that the sputum was less viscid and easier to cough up. Of the 38 patients 5 were decidedly improved, 8 were moderately improved, 5 were slightly improved and 20 were not improved; 5 patients died. The most definite improvement was observed in patients with minimal and moderate involvement, that is, about 50 per cent of the patients with minimal or moderate involvement experienced some improvement.

Periarthritis of Shoulder.—Solomon and Morton compare the results in 25 consecutive patients with periarthritis of the shoulder treated with diathermy with the results obtained in 25 similar patients given roentgen therapy. With diathermy 60 per cent of the patients were relieved of all symptoms or had but a minimal amount of tenderness or pain in the region of the shoulder. The average number of diathermy treatments was nine, representing approximately three weeks of therapy. Of the patients receiving roentgen irradiation 60 per cent also were cured or definitely improved. All except 3 patients received the full course of therapy, six treatments in two weeks. The data on these patients, as the data on the patients receiving diathermy, show that the duration of the disorder, its mode of onset or the presence or absence of calcium did not materially influence the results.

Control of Cancer of Uterus.—With the conclusion in mind that the best way to discover cancer of the uterus at its beginning is by periodic examination Macfarlane sought and obtained the aid of 1,000 white women aged 30 or more. To date these volunteers have been examined at least three times, some as many as six times. Among the first thousand examinations, one disclosed a patient with an early cancer of the body of the uterus, and three revealed patients with an early cancer of the cervix. Today, after surgical intervention and radium and roentgen therapy, the 4 women are well. No other cancers of the uterus have been found. In addition to the 4 with an early cancer there were 516 women who had benign lesions; 257 had precancerous lesions of the cervix (leukoplakic areas and cervicitis with erosion). One hundred and nineteen of the women with the potentially serious lesions have been treated adequately, and the menace of cancer has been removed for them.

*Use of Pitressin in Preoperative and Postoperative Treatment. L. A. Wylie, St. Petersburg.—p. 229.

Preoperative and Postoperative Use of Pitressin.—Wylie used pitressin for the preoperative and postoperative treatment of 350 patients with abdominal disorders requiring surgical intervention. The administration of 0.5 or 1 cc. of pitressin half an hour before operation makes the approach to

and exposure of the abdominal field much easier, as less hemorrhage occurs. It has been observed that the intravenous injection of 50 cc. of concentrated dextrose solution before the patient leaves the operating room augments the effects of pitressin and aids in maintaining fluid balance. The postoperative administration of 10 depressor units of pitressin is started within four hours and continued every six hours until four doses have been administered. This procedure assures the average patient freedom from discomfort due to gas. Much less morphine or pantopon (the hydrochlorides of the alkaloids of opium, principally morphine) is needed to relieve pain and restlessness. The main problem in assuring a comfortable convalescence is the control of dehydration, ileus, shock and vomiting. When pitressin is used postoperatively the degree of dehydration seems to be lessened and ileus is decreased. Postoperative shock is best treated by the accepted preventive methods. By the total postoperative abstinence from fluids other than small quantities of warm tea, bouillon or an antacid in warm water, vomiting and excessive thirst are lessened and with the administration of pitressin and dextrose solution these annoying symptoms are almost entirely absent.

Epididymitis Caused by Pneumococcus.—Heckel and Preston report a case of epididymitis caused by the type X pneumococcus in which the organism which gave rise to the acute inflammatory process was apparently introduced into the urinary tract by way of the urethra during the passage of a sound. The duration of the chronic process was about twenty years. Acute inflammation immediately followed the passage of the sound. There was no history of a primary infection of the lungs or the respiratory tract. The treatment of the condition, in contrast to treatment for conditions due to a nonspecific organism or the gonococcus, is incision and drainage. For the authors' patient, because an extensive lesion contained many abscess, complete removal of the inflammatory mass, which contained the testicle, was the only procedure possible. In 5 of the 7 cases of epididymitis or epididymo-orchitis caused by the pneumococcus collected from the literature there was antecedent pneumonia or another acute primary infection external to the urinary tract.

Postmenopausal Bleeding.—Geiger states that, of 395 patients with postmenopausal bleeding admitted to the gynecologic tumor clinic of the Cook County Hospital between January 1933 and July 1940, 265 (67 per cent) had carcinoma of the cervix, 34 had carcinoma of the body of the uterus, 10 had malignant ovarian lesions, 12 had other malignant lesions and 74 had benign lesions. The total incidence of malignant lesions was 81.3 per cent. More than one third of the benign lesions were cervical polyps. In order to establish a diagnosis 345 women were subjected to biopsy, 50 to a dilation and curettage and 13 to laparotomy.

Disease of Right Kidney and Jaundice.—Derrah and Kaufman report 2 cases of obstructive jaundice in which recovery followed the surgical removal of calculi from the right kidney. At first there was an immediate postoperative diminution of the jaundice, and later the jaundice disappeared completely. An attempt is made to explain the pathogenesis of obstructive jaundice and disease of the right kidney on the close

anatomic relationship of the duodenum, the bile ducts and the right kidney. In view of this close relationship it is rather unusual that jaundice develops in so few patients with disease of the right kidney. This may be explained by the fact that the position of the kidneys is variable and that the kidneys present some degree of mobility during respiratory movements and during changes in the posture of the body. These factors reduce the possibility of continuous pressure on the duodenum from a distended renal pelvis. In the authors' 2 patients the long history of calculous disease suggests that sufficient perinephritis was present to fix the kidney in one position.

Aniline Dyes for Hunner Ulcer.—Davis used aniline dyes as instillations or irrigations for the treatment of 16 patients with Hunner ulcer. Treatment was immediately followed by a painful reaction or a period of increased distress of the bladder. The reaction was followed by definite and unmistakable improvement for two to fifteen months in 15 of the 16 patients. However, the improvement was in turn followed by a relapse. Only 3 patients have remained well for ten, five and five months, respectively. The condition of the sixteenth patient became distinctly worse, as evidenced by a prolonged period of increased distress and then a return to the status quo without an intervening period of improvement. The author makes no claims as to the value or the efficacy of dyes of the triphenylmethane group in the treatment of submucous ulcer. However, he points out, instillation of or irrigation with the dye is a less formidable procedure than fulguration, and probably when the identity and the concentration of the dye best suited are known better the method might serve a useful purpose.

Treatment of Hunner Ulcer.—According to Kreutzmann, high voltage roentgen therapy of the Hunner ulcers of 5 women and 1 man produced complete relief in 3 of the women for seven, eleven and twelve months, respectively. The dose varied from 1,200 to 4,200 roentgens. In no case was the relief permanent. The disadvantages of this method of treatment are the limitation of dosage and the production of the menopause in women.

Mass Roentgenography of Service Men.—On the basis of the roentgenograms of all selectees and national guardsmen in two army corps areas Mercer estimates that there are between 5,000 and 15,000 persons with pulmonary tuberculosis among the million men who are now in the service but who have not had roentgenograms of the chest made. To prevent the spread of tuberculosis in the Army, Navy and Marine Corps the 5,000 to 15,000 persons should be found and weeded out before further infection occurs. In discussing the best method for mass roentgenography the author considers only the three rapid low cost methods: the photofluorographic methods using the 35 mm. or the 4 by 5 inch (10 by 12 cm.) film and the roentgen method using the 14 by 17 inch (35 by 43 cm.) paper film. Per exposure the 35 mm. film is said to cost about 1 cent, the 4 by 5 inch film about 5 cents and the 14 by 17 inch paper film 25 cents. If it costs \$10,000 to exclude a man with tuberculosis from the service the most expensive method appears to be the most economical; for example, there is a

difference of \$2,400 in the cost of the roentgenograms of 10,000 men made by the most expensive and by the least expensive method. If the use of the more expensive film resulted in the finding and rejecting from the service of only 1 service man more per 10,000 men than the use of the least expensive film would permit it would save the government \$7,600. From published studies it appears that out of 100 cases of minimal tuberculosis revealed through the use of the 14 by 17 inch roentgenogram at least 1½ cases would be missed through use of the 4 by 5 inch miniature photo and at least 5 through use of the 35 mm. microphoto.

Neurosurgical Treatment of Low Back Pain.—From his experience with 20 cases of low back pain Rowe suggests that the diagnosis of an intraspinal lesion producing low back pain rests on three points: (1) a history of intermittent pain in the back, with sharp paroxysms in the distribution of the sciatic nerve, associated with numbness or weakness of the affected leg and persisting in spite of conservative treatment; (2) definite changes on careful neurologic examination, and (3) roentgenographic changes following the subarachnoid injection of a contrast medium. Adequate neurosurgical treatment of patients with such pain may be expected to result in the relief of pain (complete in 75 per cent and definite in the remainder) and the return to work of about 75 per cent of the patients with a lesion of the intervertebral disk and most of the patients with pain due to spinal arthritis.

Sulfathiazole in Dermatoses.—The Robinsons used a 5 per cent sulfathiazole ointment for the treatment of the dermatosis of 94 patients. Fifty-eight had pyoderma, 26 had other conditions complicated by secondary coccogenic infection and 10 had various infections not related to coccogenic infection. Eight did not return after the first visit. The healing of the lesion of 48 patients with impetigo contagiosa or ecthyma indicated that the method is effective. The lesion of only 1 patient failed to heal. The shortest time in which impetigo contagiosa healed completely was three days and the longest period was thirty-two days; the condition of the patient with the latter healing period was complicated by tuberculosis ulcerosa, severe secondary anemia and adverse environment. The dermatosis of the rest of the patients involuted in five to eight days, with the exception of that of 2 with carbuncles which had been incised, but even in them healing was complete in fourteen days. The primary condition of the 26 patients with secondary pyodermic infection was not benefited by the treatment with sulfathiazole ointment, but the complicating secondary infection was con-

trolled. The authors believe that the results were equal or slightly superior to those obtained with gentian violet and far superior to those obtained with ammoniated mercury ointment. The sulfathiazole ointment was valucless in inguinal granuloma, epidermophytosis, uncomplicated contact dermatitis, indurated erythema and herpeticiform dermatitis. Good results were obtained in 2 patients with chancroid and 1 with tinea kerion. No trace of sulfathiazole was revealed in the blood stream after continuous treatment for one week.

Diagnosis of Gonococcal Infections.—Weiss and Colvin make a plea for the wider use of the cultural method for isolating the gonococcus. They base their belief that the method is more accurate than the generally used direct smear on the following data: Of 13,783 cases collected from the literature in which direct smears and cultures were made, the diagnosis of gonorrhea was justified in 4,482. In 1,194, or 26.64 per cent, only a positive culture was obtained. Only a positive smear was obtained in some 471, or 10.52 per cent. An epitome of these figures shows that of the 4,482 cases of gonorrhea in 3,288, or 73.24 per cent of the total, the diagnosis could have been made by the smear alone; in 26.64 per cent only a positive culture was secured from the material examined. Therefore, some 89.48 per cent, or 4,011 cases, could have been diagnosed by the culture method alone. Furthermore, of 621 specimens examined for the gonococcus at the Touro Infirmary 119, or 19.66 per cent, were positive; 38 specimens produced a positive culture as well as a positive smear, whereas 33 gave only a positive smear. In some 48 specimens demonstration of the gonococcus was possible by the culture method alone, that is, a positive culture was obtained whereas the smear showed no intracellular gram-negative diplococci. Therefore, examination by the direct smear alone would have rendered only 71 positive diagnoses, missing 40 per cent of the cases.

Evaluation of Histaminase.—Fox declares that the data obtained from seventy fellows of the American Academy of Dermatology on 962 patients with dermatosis treated with histaminase show that 15.39 per cent of the patients obtained temporary improvement, 10.49 per cent permanent improvement and 74.12 per cent no improvement. There are some indications that the drug may be useful for the management of serum sickness, angioneurotic edema, sensitivity to foods and drugs and physical allergy.

Colon Bacillus Septicemia with Cholecystitis.—Lipshutz and Kaplan state that colon bacillus septicemia associated with acute disease of the biliary tract may occur in three forms: as an acute and persistent septicemia from the outset, as a temporary bacteremia immediately after trauma to an area infected with colon bacilli and as a terminal bacteremia. They report 3 cases of the first type. The condition in these cases is

characterized by the abrupt onset of severe or of mild abdominal pain accompanied by chills, fever and intense toxemia. After a few days, signs which suggest the primary focus in the gallbladder may be so masked as to make diagnosis difficult. Immediate cholecystectomy appears to be the only treatment. Cholecystectomy saved the authors' first patient, who was unquestionably moribund, and after cholecystectomy the infection of the second patient subsided rapidly. The death of their third patient was attributed to perforation of the gallbladder and subphrenic abscess rather than to septicemia. They believe that an earlier diagnosis and an immediate operation might have saved this patient.

Complication from Use of Glove Powder.—Byron and Welch discuss the miliary granulomatous lesions resembling tubercles observed in old abdominal incisions of 4 patients. The finding of talcum powder in the pseudotubercles of the peritoneum in 2 patients with regional ileitis suggested to them that the implanting of talcum in such patients may be enhanced because multiple operations are often necessary before resection is done. Talcum may be responsible for at least part of the pathologic picture. Although glove powder may be responsible for these surgical complications the advantages of the powdered glove over the wet glove technic are too great, in the authors' opinion, to recommend a change to the latter, and therefore they suggest that a minimum of powder be used in preparing and in putting on surgical gloves and that the gloves be washed carefully after they are put on in order to eliminate as much powder as possible.

Subcostosternal Diaphragmatic Hernias.—Harrington encountered 4 adults (64, 46, 34 and 27 years of age) with subcostosternal hernia among 270 with various types of diaphragmatic hernia. The patients, 2 men and 2 women, had no history of trauma. One of the women had an esophageal hiatus diaphragmatic hernia as well as the subcostosternal hernia. The operative approach for the repair of the hernia was abdominal in all 4 patients. The sac was removed from 2 and it was left in place in 2. The herniated viscera were replaced and the opening was repaired in all 4. There were no operative deaths or subsequent recurrences.

Uterine Contractions of Late Pregnancy.—Murphy studied with the Lörand tocograph the uterine contractions of 129 women in the ninth and tenth lunar month of pregnancy. He observed that the women who did not experience contractions had shorter labors than the average. The contractions exhibited a wide variation in their measurements from woman to woman. However, a relation did exist between the nature of the uterine motility and the length of labor. Tension was observed to have no value in the prediction of the duration of the labor, whereas knowledge of the contractions was helpful. The short labor was usually preceded by infrequent, rhythmic, long and strong contractions. Furthermore, it appeared that

contractions, regardless of their strength, which rose slowly to a maximum and fell away at the same rate were indicative of a more efficient kind of activity during labor than the ones which rose and fell quickly, suggesting that a long contraction is better than a short one.

Fitness, Fatigue and Recuperation.—Hellebrandt and Karpovich suggest that the average man lives and works on a plane below his peak capacity. The question which arises is whether the use of ergogenics is hazardous if they improve the output of work by eliminating fatigue. The difficulty resides in the differentiation between "normal limits of fatigue set by the body" and the variable terminuses set by the mind. Wisely administered, an ergogenic may be life saving. When an acute emergency exists it may be wiser to resort to ergogenics than to abandon the exhausted. In sports any artificial intoxicating stimulant probably should be avoided, but, the authors point out, the same principle does not apply to life and death exhaustion problems associated with war. Ergogenic aids that augment work capacity by improving the condition of the machine are the safest and most physiologic. Those which push the person beyond normal endurance are potentially dangerous and should be reserved strictly for emergency use. The most enduring gain can probably be attained by systematic physical training which arouses a desire for fitness.

Wartime Anesthesia.—Phillips states that anesthesia in time of war differs from that in times of peace in that the anesthetic must be easily carried and administered. It should preferably be nonexplosive. Spinal and intravenous anesthesia play an extremely important part in modern warfare and therefore at least 25 per cent of the men in all medical units should be well acquainted with the administration of these two types of anesthesia.

personal or a positive family history of allergy, while 20 per cent had a positive history in both instances. The corresponding figures for the psychotic patients were 25 and 0 per cent and 17 and 0 per cent for the control group. The association of seizures and hypersensitivity suggested a relationship between epilepsy and allergic disorders. Intramuscular desensitization, combined with specific elimination, was tried in 12 of the 24 epileptic patients. The results were encouraging without being spectacular. Some degree of desensitization was achieved in 9 of the 12 patients; in 4 the response amounted to a definite improvement (alleviation of symptoms). One patient has had only a single seizure in the last year, whereas before treatment the monthly average had been eight. Generally most of the patients were having fewer fits and several admitted feeling better. Generally they were quieter and conducted themselves more rationally.

Polyridiculoneuritis: Case. W. Bridgen.—p. 454.

Ligation in Patent Ductus Arteriosus.—Bourne and his associates combined surgical intervention with sulfapyridine therapy for 2 patients with infection of a patent ductus arteriosus. The first patient has been an active working citizen free from cardiovascular symptoms for four months. There has been some persistence of hematuria from coexistent nephritis. The second patient has remained well for eleven months.

Crush Injury with Recovery.—Maitland reports the recovery of a man of 40 from severe renal failure resulting from being pinned by debris across the right thigh and the right side of the trunk. The patient also had a lesion of the right brachial plexus and pulmonary concussion. Protein was withheld, fluids were forced and injections of adrenal cortex extract were given. A large proportion of fluid (25.5 liters) given between the seventh and the fifteenth day was retained without any decided increase in the edema, although anasarca was present between the sixteenth and the twenty-eighth day of illness. Improvement began on the tenth day, and four months after the injury the patient is able to be up most of the day. Recovery was made in spite of intercurrent bronchopneumonia and a streptococcal infection of the throat. In spite of treatment anemia persists, suggesting some renal damage not detectable by tests of renal function. Almost all the extensor power of the affected thigh has been lost, although the thigh is anatomically normal. The renal failure in such cases may be attributed to vascular stasis, lack of fluid intake during the period of burial and flooding of the circulation with protein from damaged muscle.

Dietetics.—According to Mottram, a "peasant diet," rich enough in carbohydrates to supply energy needs and consisting of whole meal bread (fortified with calcium), cereals, potatoes, legumes, some animal protein, milk ($\frac{1}{4}$ pint [125 cc.] daily) and vegetables, is theoretically and experimentally satisfactory for the healthy adult. Such a diet is being forced on the nation by government rationing. Until it is proved or disproved that such a diet is sufficient for children it will be wise not to allow the child's daily intake of milk to fall below 1 pint. The vitamin C intake of infants and small children can be made adequate with black currant juice or purée of the juice of turnips.

Pneumonic Plague in the Kalahari.—Gale discusses the history of an outbreak of pneumonic plague in the Morokwen Native Reserve (36 deaths and 1 recovery), the origin of the outbreak, which probably was in veld rodents, and the prophylactic use of live vaccine. The diffusive power of the outbreak was low; for example, 2 or 3 men who slept for several nights in the same hut as 1 dying from pneumonic plague escaped infection. The control measures were as follows: The whole of the Morokwen Reserve was declared a plague infected area, and all egress from it, except on special certificate, was stopped. One person broke quarantine, and this led to the infection of another village. Live (avirulent) plague vaccine was supplied, and a single dose of 1,000 million organisms in 1 cc. was given to more than 1,000 natives and 40 to 50 Europeans. Pain and generalized reaction were not complained of. Many children were vaccinated with reduced doses. Most of the 1,000 persons vaccinated at Morokwen were never exposed to any real risk. However, at least 104 persons were close contacts but did not contract plague; 20 of these were not vaccinated until seven days or more after contact. Their escape can be attributed to factors other than vaccination; 37 were vaccinated within seven days of contact and 47 prior to contact; their escape may have been the result of vaccination. Plague developed in 6 vaccinated persons; 5 of them died, 2 on the first, 2 on the third and 1 on the fourth day of illness. These 5 patients were in contact with pneumonic plague from one to six days before vaccination, whereas the patient who recovered made contact five or six days after vaccination. This patient was not given antiplague serum until the fourth day of her illness.

Bacillary Dysentery. C. Berge and J. Fauconnier.—p. 103.

Typhus Treated by Serum.—The serum employed against exanthematous typhus by Durand and Balozet is obtained by subcutaneous or intravenous inoculations of horses with rickettsias from the lungs of mice infected via the respiratory tract with murine or epidemic virus. Experimentation having shown that the neutralizing properties of this serum greatly exceed those of human convalescent serums, it seemed advisable to try it in human subjects. In complete ignorance of the quantity of serum required, the authors began with massive doses of 100 to 200 cc., with perhaps a new injection the following day. Later they reduced the dose, and in the end they gave only 100 cc. in a single injection as soon as possible. The injection is made by preference into the crural quadriceps, the resorption being more rapid and the pain less annoying than if injection is made into the flank. The serum was used in the course of an epidemic during the first months of 1941. In 102 native born Tunisians with exanthematous typhus cure was obtained rapidly in two to four days on the average. The mortality was greatly reduced. This could be ascertained by comparison with 161

HOUSE COMMITTEE

patients who were treated in the same manner except that they did not receive serum. The gross mortality rates were 3.92 and 12.42 per cent, respectively; the corrected percentages were 3.92 and 14.28, respectively. Even if one adds the patients on whom the serum was first tried the mortality was only 4.46 per cent; that is, it was about a third of the rate among the patients not treated with serum. With the 8 Europeans on whom the serum treatment was used the results were not as favorable as in the native born patients, but their number was too small for one to arrive at definite conclusions.

*Catamnestic Investigations in Late Syphilis: Fate of Syphilitic Patients. E. Rajka and A. Orbán.—p. 1.

Aspects of Atypical Cases of Dermatitis Herpetiformis. C. H. Beck.—p. 70.

*Chronic Intermittent Treatment of Dyshidrosis with Mixed Vaccines. A. Dósa.—p. 75.

Fate of Syphilitic Patients.—Rajka and Orbán made follow-up studies on 200 syphilitic patients in order to determine the efficacy of the treatment. The earliest date of the control examination was the fifth year after the infection, when a stable condition of the cerebrospinal fluid could be expected. However, since the reaction of the cerebrospinal fluid may turn positive later and since cardiovascular changes likewise usually appear later, control examinations must be repeated later than the fifth year. The patients investigated were workers and craftsmen who attended an outpatients' hospital in Budapest. Complete cure was obtained in 21 per cent, or in 37.5 per cent if patients with so-called neurologic residues are included. These conditions may be regarded as residues of processes that have taken their course, provided the results of all the tests (of the blood and the cerebrospinal fluid) have remained negative after prolonged supervision. A positive seroreaction without clinical symptoms was observed in 9.5 per cent of the patients; 6.5 per cent of these had received intensive treatment and thus must be regarded as seroresistant patients who required treatment with specific and nonspecific methods. In 5.5 per cent (including 2 per cent of seroresistant patients) reactivation of seroreactions was observed. Successful provocation indicates latent seropositivity. Clinical symptoms were observed in 53 per cent of the patients; 35 per cent showed active neurosyphilis and 32 per cent cardiovascular syphilis. In 26.5 per cent of all the patients and in 60 per cent of those with active neurosyphilis the reaction of the cerebrospinal fluid was positive. Only half of those with neurosyphilis and a positive reaction of the cerebrospinal fluid showed a positive reaction of the blood. It proved difficult to classify the observed neurologic sequels of syphilis under the classic pictures of neurosyphilis. One third of the patients presented rudimentary symptoms which did not correspond with the classic pictures and were designated as neuroresidues. The question whether these residues were the signs of active processes or sequels of processes which had taken their course had to be decided in each case by further examination. There is no therapeutic method which insures cure in 100 per cent of cases. The question of who incurs neurosyphilis and what factors are decisive in the involvement of the central nervous system is, as Nonne says, as yet unsolved. Present day therapeutic procedures offer, in a third of the cases, no protection against the nervous diseases originated by syphilis. Nevertheless, it could be demonstrated that the number of complete cures was the greater and the sequels the lesser the earlier treatment was begun and the more intensive and systematic had been the initial treatment.

Treatment of Dyshidrosis with Mixed Vaccines.—Dósa tested patients with dyshidrosis for allergy against fungi. At first he made the intracutaneous tests with fungus extracts only in cases in which fungi had been detected in the dyshidrosis vesicles, but later, when positive cutaneous reactions had been obtained in cases in which fungi had not been observed in the vesicles it was concluded that in these cases fungi also play a part, and all patients with dyshidrosis, irrespective of the results of microscopic and cultural examination, were treated with a vaccine composed of mixtures of numerous fungi and bacteria. The author began with intracutaneous injections of 0.1 cc. and

gradually increased the doses to 2 cc. The larger doses were distributed to several sites in the thigh. The treatment was administered in a chronic intermittent manner in series consisting of twenty to thirty injections. The results obtained with this treatment were better than the results with any other therapy. The author thinks this is because the injections increase the active immunity.

*Reactivation of Wassermann Reaction in Cerebrospinal Fluid, Observed After Intraspinal Injection of Phenolsulfonphthalein. M. Felici.—p. 228.

Amount of Ascorbic Acid in Cerebrospinal Fluid: Researches. R. Grisoni and C. L. Cazzullo.—p. 241.

Reactivation of Wassermann Reaction in Cerebrospinal Fluid.—Felici reports the results of serologic examination of the spinal fluid in 10 patients with neurosyphilis. There was a history of syphilis in all the patients. One patient had tabes and 1 had dementia paralytica. The cerebrospinal fluid of 3 patients showed slight changes before the intraspinal injection of phenolsulfonphthalein. The Wassermann serologic test gave strongly positive results in 4 cases of the 6 in which the Wassermann test on the blood serum gave negative results, and the Müller, Kahn and citochol tests on the blood serum gave positive results. An aseptic meningitis was provoked by the intraspinal injection of 5 cc. of a 5:1,000 phenolsulfonphthalein solution, which was given after the withdrawal of 10 cc. of cerebrospinal fluid. A lumbar puncture was performed twenty-four, thirty-six or forty-eight hours after the injection, when the fever was at its highest. In a few cases, in which the fever lasted for three days, the lumbar puncture was repeated seventy-two hours after the injection, and in all cases it was again performed seven or ten days after the injection. Subjectively the patients complained of headache, spinal pain and paresthesia of the legs. They exhibited rigidity of the neck, absence of tendon reflexes in the legs and paralysis of the sphincter of the bladder. Only 1 patient had vomiting. The symptoms disappeared in all cases within forty-eight hours. The fever disappeared within three days in almost all cases. The cerebrospinal fluid, which was obtained by lumbar puncture, was observed separately in the natural condition and again after being inactivated by being subjected to a temperature of 56 C. for half an hour. It exhibited the following changes: (1) a moderate increase of the albumins, the globulins and the cells, especially the lymphocytes, (2) turbidity and a tendency to flocculation in the second or the third of the tubes used in the mastix test and (3) a moderate pink shade of the fluid for the first forty-eight hours after the injection. Within six days the cerebrospinal fluid became normal or almost normal in all cases. The Wassermann, Müller and Sachs-Witelsky tests gave constantly negative results with all the different specimens of the cerebrospinal fluid, whether in the natural condition or inactivated. The negative results obtained by the author in attempting to reactivate the cerebrospinal fluid with the use of phenolsulfonphthalein agree with those previously reported in the literature in cases in which distilled water or a bismuth compound was used. Because the observations were carried on with a careful technic and all the patients had serologic syphilitic reactions and most of them exhibited precise clinical symptoms of neurosyphilis, the author concludes that the reactivation of the cerebrospinal fluid by the intraspinal injection of distilled water, bismuth compounds and phenolsulfonphthalein is not possible and that consequently the test does not have any diagnostic value of neurosyphilis.

*Cyanotic Chronic Bronchopneumopathy: Clinical and Physiopathologic Study. J. Fernandes Pontes, M. Jamra and A. Carvalho da Silva.—p. 651.

Cyanotic Chronic Bronchopneumopathy.—Fernandes Pontes and his collaborators report 2 cases of Ayerza's disease which were observed in the bronchopulmonary period. No other case of the disease observed in this period has been reported in the literature. In the cases reported by the authors the symptoms were typical. Bronchitis had lasted for forty and twenty-two years, respectively, and the bronchopulmonary symptoms

for about one year. There were dyspnea and acute cyanosis, especially of the lips, face, ears, hands and feet. The respiratory elasticity of the thorax was greatly diminished. The roentgenograms of the lungs showed the changes proper of chronic bronchopulmonary emphysema and sclerosis. There were polyglobulia and macrocytosis. The functions of the heart were normal, but the roentgenograms showed dilatation of the right ventricle and enlargement of the heart. The electrocardiograms showed a shift of the electrical axes to the right and a P wave of increased amplitude in the second and third leads. The Wassermann reaction was negative in both cases. By means of gasometric analysis and hemodynamic determinations the authors found that in their patients the vital capacity was diminished, the dead space of the respiratory bed of the lung was increased and the amount of current air was diminished. There were changes in the pressure of oxygen and carbon dioxide in the alveolar air, hypoventilation of the alveolar air and hypoxemia. There was also hyperplasia of the bone marrow, as it was verified by examination of marrow tissue obtained by sternal puncture. The authors believe that chronic obstructive bronchopulmonary emphysema is the cause of the symptoms of Ayerza's disease, especially cyanosis. According to them, Ayerza's disease is not a clinical entity but a form of chronic obstructive bronchopulmonary emphysema in patients with a constitutional lability of the cardiorespiratory apparatus and a constitutional hyperplastic reactivity of the bone marrow. Syphilitic arteritis of the pulmonary artery may be found as an associated condition in cases of Ayerza's disease, but it is not the cause of the disease. Cyanosis, which is the most evident symptom, is due to anoxic hypoxemia from hypoventilation of the blood. It diminishes when the patients inhale oxygen under pressure for ten or twenty minutes. Hypoxemia stimulates the bone marrow to an erythroblastosis hyperplastic reaction and consequent polyglobulia. The macrocytic changes of the erythrocytes are due to the physicochemical changes of the blood.

Enterogenic Tetany. H. W. Hotz.—p. 296.
*Therapy of Malignant Diphtheria: Blood Transfusion or Adrenal Cortex Extract. W. Behr.—p. 310.

Prophylaxis of Heat Disorders.—To determine the efficacy of prophylactic measures against heat disorders, Böttner and Schlegel made experiments on 25 persons. They found that the parenteral administration of adrenal cortex extract prevents, or at least greatly retards, the development of heat exhaustion and heat stroke, because the extract improves the physical heat regulation and stabilizes the circulation. Orally administered extract did not have this effect. Attempts to support a heat impaired circulation with strophanthin and epinephrine failed to produce satisfactory results. The occasionally observed action of strophanthin was of only short duration. In cases of heat convulsion the administration of adrenal cortex extract is not advisable because of the exhaustion of the sodium chloride and water economy. In order to fill the exhausted water and sodium chloride depots, physiologic solution of sodium chloride should be administered. In heat stroke and heat exhaustion, sodium chloride solution was likewise tried. The efficacy, although not always convincing, was evident in some cases.

Therapy of Malignant Diphtheria.—According to Behr, malignant diphtheria differs from the ordinary pharyngeal form in that serum therapy comes generally too late to be effective, the intoxication being severe almost from the onset. Numerous therapeutic measures have been suggested to increase the defense powers of the organism, to aid detoxication and change the reaction. Only two of these are still given serious consideration: (1) blood transfusion and (2) the administration of adrenal cortex extract and ascorbic acid. The author evaluates these methods on the basis of the available literature and of his own observations. He is unable completely to corroborate the highly

favorable experiences with blood transfusion made at other clinics. Its influence on the local process and on the general condition is not convincing. The fulminant course is apparently not arrested; complications are neither prevented nor rendered particularly mild. Late fatalities are not prevented, and the mortality is decreased at the most by 10 to 12 per cent. However, blood transfusion cannot be designated as entirely valueless. Adrenal cortex extract and ascorbic acid are administered not only in order to prevent the adrenocortical insufficiency which threatens, because of the diphtheria toxemia, but to promote detoxication and increase the defense function of the organism by modifying the reticuloendothelial system. Administration of the extract and the acid is intended as a prophylactic and detoxicating measure and as treatment for the circulatory deficiency, because it is thought that adrenocortical insufficiency is an important factor in diphtheritic circulatory impairment. Adrenal cortex extract and ascorbic acid were administered to 29 patients with malignant diphtheria (extremely severe in 20 and moderately severe in 9). Even large doses and early application did not reliably arrest the fulminant course. Complications were not prevented. Fatality rates reached 55 per cent in the cases of severest diphtheria. The combined use of blood transfusion and medication with adrenal cortex extract and ascorbic acid however, is most promising in the severest forms of diphtheria. This combination treatment seems to render the diphtheria milder and to arrest the fulminant course.

- Orthopedic Investigations on Twins. I. Kopits.—p. 130.
Treatment of Habitual Dislocation of Shoulder. J. Janěk.—p. 167.
*Inflammatory Lordosis. G. Schramm.—p. 172.

Inflammatory Lordosis.—Schramm directs attention to unilateral inflammatory changes of bone on articular processes of the lumbar vertebral column as a cause of severe motor disturbances. A tabular report summarizes the chief aspects of all 7 cases so far reported. The disorder occurs in children of the prepuberal or the early puberal age. It is noteworthy that the process is always localized in the two lowest lumbar vertebrae. Infections seem to play a part in causation. The fact that in Storck's case roentgenoscopy gave negative results is of no particular significance in view of the fact that in 2 of the author's cases the clinical symptoms preceded the positive roentgenologic aspects by a year. The author agrees with Hohmann that the limitation of the movement of the lumbar vertebral column is the result of a reflex contracture of the muscles in the region of the diseased vertebrae. Discussing the treatment he says that immobilizing and relieving measures not only are entirely worthless but even exert an unfavorable effect. In cases in which roentgenoscopy discloses severe changes, Hohmann's operation (removal of diseased bone tissue and fastening of a piece of the tibia to the spinal processes of the lumbar vertebrae) is the method of choice. In cases in which a negative result of roentgenoscopy indicates the absence of serious changes of bone, stretching of the shrunken sacrospinal musculature may overcome the fixation of the lumbar lordosis. A mild form of chronic osteomyelitis of the vertebral arches and articular processes was found to be the cause of the fixed lordosis in 4 cases, and so the author suggests the term inflammatory lordosis.

*Early Diagnosis of Tuberculous Coxitis During Childhood. K. Lindemann and A. Dieckvoss.—p. 225.
Surgical Treatment of Certain Forms of Arthrosis Deformans of Hip Joint. M. Hackenbroch.—p. 238.

Tuberculous Coxitis During Childhood.—Lindemann and Dieckvoss point out that roentgenoscopy during the early stages of tuberculous coxitis in children regularly discloses, besides atrophy of the juxta-articular osseous tissues, an enlargement of the nucleus of the femoral head epiphysis. This enlargement is not simulated by projection but is real, resulting from increased endochondral growth in connection with the chronic inflammation of the joint. The demonstration of this enlargement in the stage of the disease before the tuberculous destruction can be observed facilitates the early diagnosis of tuberculous coxitis in children.

*Influence of Pilocarpine on the Glutathione Content of Blood, Liver and Spleen. N. Izaki.—p. 503.

*Concerning the Effect of Histamine on Blood Vessels. S. Yoneda.—p. 519.

Pilocarpine and Glutathione.—Izaki reports that small doses of pilocarpine injected subcutaneously depress the reduced glutathione in the blood, liver and spleen but elevate the concentration of oxidized glutathione. When larger doses are given the reduced glutathione decreases slightly, while the oxidized and total glutathione contents are depressed considerably. This latter effect of pilocarpine is inhibited when atropine or scopolamine is simultaneously administered; phenobarbital exerts no such noticeable influence. Large doses of pilocarpine cause an increase of the glutathione in the liver and the spleen. When atropine or scopolamine is given with pilocarpine the action of glutathione in the spleen is inhibited; atropine inhibits the oxidized form of glutathione in the liver, and scopolamine acts on the reduced form. While phenobarbital causes a great acceleration of the reduced glutathione action in the spleen and liver its effect on the oxidized form is inhibitory. From these results it may be inferred that the influence of pilocarpine on the glutathione action of the blood, spleen and liver is intimately related to stimulation of the peripheral sympathetic system; this action involves stimulation of the centers in the midbrain.

Effect of Histamine on Blood Vessels.—Yoneda reports perfusion experiments on the effect of histamine on the blood vessels of intact dogs under urethane anesthesia and of excised organs. The most noticeable result under these conditions was the dilator effect of histamine in small doses and its constricting effect in larger doses. The dilatation of vessels seemed most pronounced in the capillary areas, but similar effects were observed in the arteries and veins, uninfluenced by the autonomic nervous system. Since the action of histamine does not appear to depend on the presence of muscle fibers on the walls of these vessels, its effect presumably involves a direct action on the vascular endothelium. Its constricting effect is most pronounced in the experiment of the perfusion of excised organs, the effect becoming more and more noticeable as the perfusion progresses, particularly in vessels of the intestine.

Hepatic Abscess in the Tropics. W. M. Pruys.—p. 1894.

*Culture of Rickettsias in Duck Eggs. R. Gispén.—p. 1907.

*Fatal Poisoning by Bite of Sea Snake (*Enhydrina schistosa* [Daudin]). H. Bokma.—p. 1926.

Culture of Rickettsias in Duck Eggs.—Gispén employed duck eggs in the culture of rickettsias and viruses. It was found that the chorioallantois of duck eggs is quite suitable for the culture of viruses and rickettsias. The use of duck eggs has several advantages over the use of hen eggs: The duck embryo is more viable under laboratory conditions; virus infection kills it less rapidly; its incubation requires twenty-six or twenty-seven days, that is, five days longer than the chicken embryo's; the egg membrane available for inoculation is larger and thus produces a larger quantity of virulent material. Scrub typhus rickettsias and Sumatran mite fever rickettsias, which failed to grow in hen eggs, were readily propagated on the chorioallantois of duck eggs.

Conservative Treatment and Pneumothorax in Cavertous Phthisis.—Cold compared two groups of patients with recent unilateral cavernous pulmonary tuberculosis which show practically complete conformity with regard to sex, age, dura-

tion of symptoms, temperature, extension and density of process, size and number of cavities, location of cavities, degree of expectoration, sedimentation rate, the hospital in which they were treated and the period of observation. One of these groups was given pneumothorax therapy while the other one was under conservative treatment with ordinary sanatorium care. The comparison demonstrates the superiority of the pneumothorax treatment. In patients with extremely dense infiltration the results are poor with either form of treatment. The more the cavity dominates the clinical picture, the more valuable is the pneumothorax treatment. In the presence of small cavities, pneumothorax produces cure in 79 per cent of the patients, conservative treatment in only 65 per cent. If the cavities are large (more than 3 cm.) pneumothorax produces favorable results in 74 per cent, conservative treatment in only 33 per cent. The results are best in patients with adhesion-free pneumothorax, but even in the presence of nondivided adhesions and large cavities the results are decidedly better with pneumothorax therapy than with conservative treatment. In patients with recent not entirely unilateral cavernous tuberculosis and in those with the disease in chronic form the results of pneumothorax are far worse than in patients with recent unilateral cavernous tuberculosis. The results of pneumothorax are not much better in these patients than are those of conservative treatment.

Primary Pulmonary Tuberculosis.—Isager discusses the problem of primary tuberculous infection and its ultimate evolution. His observations, which were made in a dispensary of northern Jutland (Denmark), concerned one series of persons selected from a tuberculous milieu and another group of infected persons whose environment was free from tuberculosis. From tuberculous environments he selected 100 subjects, 75 of whom were less than 15 and 25 of whom were over 15. Generally the tuberculous infection had its source in the family, but in some cases it had taken place during a stay with a family in which there were persons with tuberculosis. It was found that the morbidity of primary infection is great in a tuberculous environment, particularly in persons over 15, of whom almost one third (8 of 25) became ill, whereas of 75 under 15 years only 12 became ill. The author also made studies on students who came from nontuberculous surroundings. Their ages varied from 8 to 20 and were about the same as were those in the first group. Of 613 students who had had a negative Mantoux reaction during the first examination 169 gave a positive one the following year, but none of those who had a primary infection showed signs of impaired health and none had pleurisy or erythema nodosum. The author concludes from these two series of examinations that the fact of being infected by living in a tuberculous environment or of being infected by a momentary contact plays an important part in the morbidity of infection. He further analyzes a series of 100 patients with destructive pulmonary tuberculosis, all of whom had tubercle bacilli in the sputum. The majority were between 15 and 45. Open pulmonary tuberculosis developed in 5 of them directly after erythema nodosum, and from this it is assumed that the open pulmonary tuberculosis developed rapidly after a primary infection. In 4 others the open pulmonary tuberculosis appeared after pleurisy. In 1 sign of a primary infection were discovered in the course of influenza which developed several months after the patient had stayed with a family of which a member had open pulmonary tuberculosis. In the other 90 patients the roentgenogram revealed nothing about the primary infection, but the histories provided some information. In persons with a familial infection, and particularly in married couples, the disease seems to manifest itself as follows: If the disease does not appear in the exposed person within a short time after the onset in the diseased person, the chances of infection decrease more and more. The same principle holds for persons working in tuberculosis hospitals or sanatoriums. The observations seem to support the opinion that destructive pulmonary tuberculosis develops to a large extent during the first years after the primary infection.

Book Notices

A Manual of the Treatment of Fractures. By John A. Caldwell, M.D., Professor of Clinical Surgery, College of Medicine, University of Cincinnati, Cincinnati. Cloth. Price, \$3.50. Pp. 150, with 76 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

In sixteen short chapters everything that is essential in the treatment of fractures is said clearly and concisely. Three chapters are taken up by general discussion on the subjects of repair, diagnostics, traction methods, splinting, anesthesia, compound fracture treatment and wound infection. They are short but unusually comprehensive. The entire field of fractures and dislocations is covered. Particularly recommended are the chapters on fractures of the humerus, the chapter on the wrist and fingers, the chapters on the pelvis and on the neck of the femur, the latter being treated with great clearness in ten short pages; the chapter on the foot and the ankle, including the fracture of the os calcis, and the chapter on injuries of the spine. They are all handled with great precision, and the style is clear and easy without being too pithy or epigrammatic. The didactic value of the book is enhanced by the fact that it makes use of the displays and posters of the primer on fractures issued by the Cooperative Committee on Fractures of the American Medical Association. Another important feature is that the illustrations are all diagrammatic and highly instructive. There is no space wasted on individual reports or roentgenograms of end results. In that respect the book may appear impersonal, but the reader cannot help but feel the powerful drive of an experienced pedagogue on fractures. It shows that almost all that is necessary can be said in a short space without the appearance of haste or hurry. It cannot be too highly recommended for the younger man who is at the beginning of his fracture career, though it must be of profit to all who read it.

The Foot and Ankle: Their Injuries, Diseases, Deformities and Disabilities with Special Application to Military Practice. By Philip Lewin, M.D., F.A.C.S., Associate Professor of Bone and Joint Surgery, Northwestern University Medical School, Chicago. Second edition. Cloth. Price, \$9. Pp. 665, with 304 illustrations; Line drawings by Harold Laufman, M.D. Philadelphia: Lea & Febiger, 1941.

The second edition of Dr. Lewin's book gives one a convincing feeling that the contents cover every phase of the potential derangements of the foot and ankle. One of the features is the emphasis on the relation between localized conditions and systemic lesions. Repeatedly the author correlates disturbances of the foot and ankle with disease found elsewhere in the body. Much space, nearly one fifth of the book, is devoted to the essentials of the anatomy, physiology and biomechanics of the foot and ankle, the basic principles underlying foot and ankle derangements and the principles of surgical treatment, and to the various types of modalities utilized in conservative therapy alone or in association with surgical work, not omitting an appreciation of the psychologic upsets that are often concomitants of injury or disease, particularly in so-called medicolegal problems. This preparatory review is so thorough that the understanding of the etiology, pathology and therapy of deformities, diseases and injuries of the foot and ankle is greatly facilitated.

The author deserves much credit for his careful selection of the illustrations. The photographs, roentgenograms and especially the line drawings always clearly and effectively depict what is discussed in the text. The numerous charts on etiology, symptomatology and differential diagnosis are exceedingly helpful in visualizing, crystallizing and establishing a lasting impression of the variety of causes and lesions under discussion. A most valuable feature of the book lies in the description of what would generally be considered minor details, such as how to strap an ankle, how to make a plaster of paris bandage, how to measure for crutches and how to teach their use, the construction and fit of shoes and the hygiene of the feet. The author has enriched the book vastly by giving the details of minor practical, but invaluable, points relative to the examinations and treatment which he has obtained from his extensive personal experience.

The simple and lucid presentation of the management of paralytic disturbances of the foot and ankle, the emphasis on

the care and treatment of peripheral vascular diseases and his thoughtful consideration of diabetic gangrene with the carefully detailed recommendations as to preoperative and postoperative medication merit special mention. There is an informative section on amputations, with a definition of the different types, their indications and the sites of election for different stages of disease. In the chapter on the military aspects of the foot and ankle the author thoroughly reviews the common disorders of the feet—not diseases—and their care, and he gives much useful common sense advice, valuable to the soldier but no less to the civilian. The author pays particular attention to the foot problems of modern warfare as now experienced by the European countries and discusses prophylaxis and treatment, not omitting the lessons which were learned by others and also by himself as a participant in the first world war.

Endocrinologia clinica. Por Aulo Pinto Viégas. Paper, 45 milreis. Pp. 292, with 53 illustrations. Belo Horizonte: Livraria Editora Paulo Blum, 1941.

This volume is a textbook on clinical endocrinology produced by a clinician from one of the medical schools in Brazil. It is liberally illustrated not only with photographs of cases and tissues but with case records from the author's practice. In general it represents a laudable attempt to produce a systematic discussion of clinical endocrine disturbances with an understanding of anatomy, physiology, chemistry and pathology as the background for rational therapy. Liberal citations from the literature not only of Brazil and other South American countries but from the literature of North America and Europe are to be found chapter by chapter. The author is evidently alert to the problems which have been intensively discussed within the last year or two by endocrinologists and other clinicians.

A few criticisms of the book will illustrate the type of difficulty that may be encountered. In several places there are confusions about the exact authors concerned with work when the spellings of authors' names are too nearly alike. These spellings in foreign languages often contribute difficulty, and the same problem exists with some technical words. The reviewer is tempted to suggest that proof reading was not careful enough. The author also has shown slight confusion about the physiologic significance of such materials as the pressor and oxytocic factors in the posterior pituitary.

In many places one finds laboratory results given with too many significant figures. So, for example, the height of human beings is recorded in terms of millimeters, where centimeters is probably the smallest unit which should be employed. The reporting of basal metabolism tests is down to tenths of 1 per cent when the method is not accurate to less than 3 or 4 per cent. In several cases the diagnosis of hypothyroidism appears to be based on too little evidence, since the basal metabolic rate is not below normal and the cholesterol values are not nearly outside the normal range of variations quoted by the author or known by others. There is also confusion of cretinism and juvenile myxedema.

A chapter on diabetes is contributed by another, Dr. O. Moreira, who follows essentially the pattern of Dr. Joslin in his methods of management. Details of diabetic therapy are not made clear, and the author takes the stand that protamine zinc insulin should not be used in complicated diabetes or for patients who have already begun the use of standard insulin. With this, most physicians would now disagree. The author also gives assent to a generalization which is unjustified, namely that the hypoglycemic reactions to protamine zinc insulin and standard insulin differ qualitatively and uniformly.

In the discussion of obesity the author tends to assume hypothyroidism without adequate evidence in some cases. In his plans of a diet for pregnancy to prevent excessive weight in the infant he gives what any one would consider an inadequate diet for the sake of the mother, and in the discussion of dinitrophenol he considers it harmless and a useful substitute during rest periods from the employment of thyroid. These conclusions would not be considered rational at present. He feels that the dienecephalic factors in obesity are probably secondary to endocrine control but gives no evidence for this point.

In a final chapter listing many commercial preparations, it is obvious that the listing is far from complete and therefore misleading, and also that the strength of the materials is not indi-

cated with dependable detail so that one can tell what type of unit one is using. There is some discrimination about these matters, but it is far from being uniformly helpful. The author has had almost no experience with diethylstilbestrol and does not recommend it. He makes no distinction between gonadotropic preparations made from chorionic sources or from the genuine pituitary or from pregnant mare's serum. There has also been no distinction made between thyroid of different types of standardization. In spite of these criticisms the book is to be commended, and it is hoped that future editions will correct many of these details.

The Chemistry of Organic Medicinal Products. By Glenn L. Jenkins, Ph.D., Dean and Professor of Pharmaceutical Chemistry, School of Pharmacy, Purdue University, Lafayette, and Walter H. Hartung, Professor of Pharmaceutical Chemistry, School of Pharmacy, the University of Maryland, Baltimore. Paper. Price \$3.80. Pp. 457. St. Louis: John S. Swift Co., Inc., 1941.

This planographed volume represents an attempt to organize the organic medicinal compounds according to the accepted scheme of chemical classification. Written for students who have had basic courses in chemistry and who are interested in the chemistry of medicinal and related products, it is intended primarily, according to the authors, for use by students in the more advanced courses in pharmacy. The fifteen chapters, which are on hydrocarbons, halogenated hydrocarbons, hydroxyl derivatives of hydrocarbons, ethers and peroxides, the carbonyl group, the carboxyl group, natural mixtures, amines, cyanides and nitro compounds, sulfur compounds, phosphorus, arsenic and antimony compounds, metallic derivatives of organic compounds, heterocycles containing one heteroatom, heterocycles containing two or more heteroatoms, and stereoisomerism, discuss the chemistry of methods of preparation, properties and descriptions of the more important compounds. In addition to presenting short dissertations on uses and modes of administration, the authors have correlated physiologic activity and chemical structure wherever there are sufficient data. Preceding the general subject matter is a list of references to published studies on general chemistry, organic medicinal products, chemotherapy, phytochemistry, alkaloids, vitamins, enzymes, pharmacology and therapeutics and other subjects. The authors have exercised good judgment in this list, in view of the scope of their book, and present a useful feature. Minor errors and erroneous therapeutic implications, especially noticeable in the sections pertaining to the sex hormones and the sulfonamides, permit acquiescence to the authors' prefatory statement "The work is not exhaustive and no claim of perfection is made." However, subsequent issues of the book will probably possess the necessary corrections and will be looked on as useful and practical additions to the literature on organic chemical compounds used in medicine.

Gynecology and Female Endocrinology. By Emil Norak, A.B., M.D., D.Sc., Associate in Gynecology, The Johns Hopkins Medical School Baltimore. Cloth. Price, \$10. Pp. 605, with 425 illustrations. Boston: Little, Brown & Company, 1941.

The combined title is used by the author because female endocrinology is now an integral and important part of gynecology. Operative technic is entirely omitted because the great majority of readers of textbooks on gynecology are not interested in the details of operations. On the other hand, diagnosis and treatment are accentuated as Novak believes most readers would wish. Functional disorders including especially the large group of gynecologic endocrinopathies are treated elaborately. The material in the book is based on the author's extensive experience as a teacher, pathologist and practicing gynecologist. The style of writing is, as always, interesting, instructive and to the point. The sections on pathology are worthy of special emphasis, but this is to be expected because Novak is one of the foremost gynecologic pathologists in the world. The illustrations are magnificent and many are in color. At the end of each chapter is a selected list of references, which were chosen with excellent judgment. Every gynecologist should be familiar with the contents of this book. Likewise every physician who treats women should have a copy of this book. Novak is to be congratulated on the excellence of the book. Likewise the publishers are to be commended for having carried out their part so well.

- **A Study of the Public Mental Hospitals of the United States 1937-39.** By Samuel W. Hamilton, M.D., Grover A. Kempf, M.D., Grace C. Scholz and Eve G. Caswell. United States Public Health Service Associated with the Mental Hospital Survey Committee. Federal Security Agency, United States Public Health Service. Supplement No. 164 to the Public Health Reports. Paper. Price, 20 cents. Pp. 126. Washington, D. C.: Supt. of Doc., Government Printing Office, 1941.

The Mental Hospital Survey Committee was composed of Drs. Walter L. Treadway, S. Spafford Ackerly, Louis Casamajor, Ross McC. Chapman, Franklin G. Ebaugh, Clarence M. Hincks, J. Allen Jackson, Lawrence Kolb, Bernard T. McGhie, Arthur P. Noyes, Winfred Overholser, Frederick W. Parsons, Arthur H. Ruggles, William L. Russell and H. Douglas Singer. The results accomplished by the survey and published in this valuable report are best described briefly in the committee's own statement of purpose:

The purposes of the survey were (1) to determine the status of the administrative organizations in various political jurisdictions and the functions which they actually perform; (2) to inform interested public officials about the standards prevailing in different states; (3) to evaluate the adequacy or suitability of institutional structures and equipment; (4) to study the adequacy of professional, subprofessional and technical personnel; (5) to acquaint those working in the hospital field with what is being done in various institutions; (6) to evaluate the educational facilities for the training of resident physicians; (7) to ascertain the measures and facilities for conduct of research; (8) to present to the medical profession a statement of the public facilities and provisions for meeting the needs of the mentally ill.

Under "Origin of Survey" is the significant statement that:

In 1936 three agencies, the American Psychiatric Association, the National Committee for Mental Hygiene and the United States Public Health Service, joined forces and projected a continent wide survey of mental hospitals. The interest and active support of several other organizations were at once enlisted. These were the American Medical Association, the American Board of Psychiatry and Neurology, the American Neurological Association, the Canadian National Committee for Mental Hygiene and the Canadian Medical Association. A joint Survey Committee was set up and at various points collaboration with the several staffs was developed, especially with the Council on Medical Education and Hospitals of the American Medical Association.

All physicians and others who are interested in the purpose and work of public mental hospitals in the United States will find this report most informative and comprehensive. The unusually clear outline and concise style makes its vast and varied data readily accessible.

Desarrollo del sistema de conducción atrio-ventricular. Por Ralfo Roberto Calcagno. Tesis de doctorado, Universidad nacional de Buenos Aires, Facultad de ciencias médicas, Escuela de medicina. Paper. Pp. 130, with 44 illustrations. Buenos Aires. A. Galdi Buffarini, 1941.

This monograph in Spanish, with an English summary, presents a review of the literature on the development of the auriculoventricular conduction system in addition to the author's own work on the calf embryo from 4 to 70 mm., based on complete serial sections of the heart. There is a comprehensive bibliography. The author points out that, as the cardiac tube and the constrictions that mark the different cavities appear, the ventricular myocardium is formed by a layer of compact tissue. This gives rise to a series of buds tending to form a second spongy internal layer. At the level of the auriculoventricular canal the outer and inner layers of the musculature are separated by a groove transforming the musculature of the canal into two tubes. The outer tube disappears completely when the pericardial mesenchyme invades this groove, leaving the internal tube as the only muscular connection between the auricular and ventricular cavities. It is from this muscular tube that the auriculoventricular conduction elements are formed. The auriculoventricular node arises in the form of a plate from the posterior part of the musculature; later, at the time that the septum intermedium appears, it is transformed into a ventrally displaced nucleus. The common auriculoventricular bundle and its two branches arise from the spongy musculature of the ventricle at the time the interventricular septum begins and they are moved upward as the septum grows, riding on top of the septum. Just before the interventricular septum fuses with the septum intermedium the auriculoventricular bundle consists of a nucleus of large clear cells, forming trabeculae. When the intermediate and interventricular septum

fuse, the common auriculoventricular bundle and the auriculoventricular node come in contact and become connected, each retaining its characteristic structure. Part of the spongy tissue of the ventricular cavity fuses with the septums and is transformed into the Purkinje elements of the peripheral network.

O método de Meduna em esquizofrênicos crônicos. Por Anibal Silveira, psiquiatra do Hospital de Juqueri. Tese de concurso à docência livre de Clínica psiquiátrica na Faculdade de medicina da Universidade de São Paulo. Paper. Pp. 150, with 14 illustrations. Juqueri, São Paulo: Oficinas Gráficas do Serviço de Assistência a Psicopatas, 1941.

This monograph is a needed contribution on metrazol convulsive therapy of chronic schizophrenia. A review of the present status of convulsion therapy is given in the introduction. There are six chapters. The first discusses the concept of schizophrenia with a critical analyses of all the diverse opinions. The second includes a detailed description of the technic of convulsive therapy employed by the author with the contraindications. The third part considers the clinical aspects of schizophrenia with a critical analysis of the forms of therapy. The fourth chapter discusses the various types of schizophrenia treated by convulsive procedure. The fifth chapter describes the experiences of the author in his cases. The sixth chapter compares the author's results with those of other authors. The book was written by the author as partial fulfilment of "venia legendi" in the Faculty of Medicine, São Paulo State University, Brazil. There is a detailed bibliography containing four hundred and twenty-one references. This book is recommended to all psychiatrists and neurologists.

Lecciones clinicas de medicina oftalmológica. Por el Dr. Carlos Charlin C., profesor de clinica oftalmológica. Cloth. Pp. 381, with 68 illustrations. Santiago de Chile: Ediciones Ereclla, 1941.

This collection of thirty short essays on various aspects of medical ophthalmology are in the form of reports of undergraduate clinics held by the author in the university clinic. They deal with the more or less unusual ocular conditions that are based on systemic disturbances such as the ophthalmic complications of various forms of avitaminosis, the ocular hysterias and the fundus changes of diabetes and arterial hypertension. Tuberculosis plays quite a role, as does malnutrition in the causation of ocular disease in Chile. Apparently the disease conditions encountered in the Chilean clinics varies considerably from those ordinarily encountered in the charity clinics of this country. In a short review of this character it is obviously impossible to deal with the particular points of each essay, but in general it may be said that the subject material of the book is presented particularly for the undergraduate or the beginning graduate student. In its make-up the volume is essentially French in character, although the printing is better than the usual Gallie form. The black and white illustrations leave much to be desired. The concluding chapter is a study of the personality of Pasteur, evidently the author's hero.

Cardiac Clinics: A Mayo Clinic Monograph. By Fredrick A. Willis, B.S., M.D., M.S. in Med., Head of Section of Cardiology, Mayo Clinic, Rochester, Minn. Cloth. Price, \$4. Pp. 276, with 35 illustrations. St. Louis: C. V. Mosby Company, 1941.

The appearance in a single volume of lectures previously scattered in the various issues of the Proceedings of the Mayo Clinic is welcome. The author's aim, as he states in his foreword, is to present a practical discussion of the heart intended for the busy general practitioner. The volume contains a combination of case reports and short philosophical dissertations on the various aspects of heart disease. The busy practitioner should find this volume valuable especially for the general admonitions. The presentation of case reports is instructive since, unlike the ordinary textbook style, this permits the discussion of individual cases and avoids the presentation of average patterns. In the author's endeavor to meet the needs of the practitioner, some of his interpretations of mechanisms are oversimplified. Nevertheless this, by avoiding polemics, offers a usable interpretation of clinical phenomena on which the findings may be fixed in the reader's mind. The general philosophic aspects are pointed and apropos and make delightful reading. This book fulfils the purpose intended by its author.

Nutrition in Health and Disease. By Lenna F. Cooper, B.S., M.A., M.H.E., Chief, Department of Nutrition, Montefiore Hospital, New York City, Edith M. Barber, B.S., M.S., Lecturer on History of Cookery, Teachers College, Columbia University, New York, and Helen S. Mitchell, B.A., Ph.D., Director of Nutrition on the Staff of the Coordinator of Health, Welfare and Related Defense Activities Federal Security Agency. Eighth edition. Cloth. Price, \$3.50. Pp. 709, with 102 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1941.

This is the eighth edition of a book which has earned for itself a place as a reliable textbook in this field. The present edition is brought up to date by inclusion of the standards recently adopted by the Committee on Foods and Nutrition of the National Research Council. There are also improvements from the point of view of new special diets and an extended study of dietary habits according to racial groups. All of the authors concerned are at present occupying positions of importance in relationship to nutrition and the national defense.

Sinus. By Russell Clark Gore, M.D. Cloth. Price, \$2. Pp. 165, with 16 illustrations. New York: Alfred A. Knopf, 1941.

This small work is intended chiefly for the intelligent lay reader. Medical students and general practitioners would find it interesting and valuable reading. Informative and authoritative, it tells its story in plain language and drives the lesson home still further by simple drawings and reproductions of roentgenograms. Starting with a discussion of important anatomic and physiologic data concerning the accessory nasal sinuses, the author devotes the remainder of the book to a detailed account of various disease conditions of these cavities. Popular fallacies are exploded, self medication is warned against and the necessity for proper medical attention is stressed. This work is in line with proper efforts of the profession to inform, in an adequately guarded manner, lay persons seeking enlightenment on various things medical.

America's Nutrition Primer: What to Eat and Why. By Eleanor Saxe. Introduction by Dr. E. V. McCollum. Cloth. Price, \$1. Pp. 95, with illustrations by the Author. New York: M. Barrows & Company, Incorporated, 1941.

Here is a collection of a few thousand words on the basic facts about the purchase and uses of food, with some "budget saver" menus, some recipes and rules. The author is a professional dietician who has been lecturing on food and nutrition throughout the nation. Most of the material submitted is quite accurate and perhaps constitutes about all that the average housewife can learn easily. There are, however, many much more complete books easily available at the same price.

Instructions in Laboratory Work in Bacteriology for Students in Professional Schools. Department of Bacteriology, University of California Medical School, San Francisco. Second edition. Paper. Pp. 147. San Francisco: J. W. Stacey, Inc., 1941.

This syllabus was prepared from sets of directions furnished to students in medicine, dentistry, pharmacy, advanced bacteriology and nursing over a period of many years. Some two hundred and fifty-six experiments are given and certain of these are assigned to meet the needs of the class in question. To this edition questions have been added which are of two types, one to stimulate the habit of analyzing experiments, the other to provide a connecting link between fields of medicine and public health and experimental procedures. The syllabus is well indexed and directions are given on the left page, leaving the right one blank for student notes. This book should prove useful to the student taking laboratory work in bacteriology.

Entre cirujanos y hospitales. Por el Dr. Jose Castro Villagran. Paper. Pp. 201. Mexico, D. F.: The Author, 1940.

This is a travelogue depicting various medical centers of the world. It sketches the scenes and atmosphere surrounding various men whom the writer has chosen to depict. The author is much impressed with the work of Böhrer of Vienna. In Munich he was much impressed with Drs. Kreuz and Keysser as well as the institutes at Hamburg and Dresden and Bayers' chemical works in Lieverkussen. Those who enjoy beautiful Spanish phraseology will like this book.

Sex Life in Babylonia. By Edwin W. Hirsch, M.D. Cloth. Price, \$2. Pp. 38. Chicago: Research Publications, 1941.

This is a superficial review of a subject on which much has been written previously. The essay first appeared in the *Urologic and Cutaneous Review*.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

FOOT STRAIN

To the Editor:—A laborer aged 25 gave a history of working in a factory the floors of which were hard cement. He had been working for about two weeks when his feet became so tender that he could do this work no longer. He also said that a piece of timber had fallen and struck him on one heel. There were two large calluses, one on each heel. One of the calluses was grooved horizontally. The main question I am interested in is the fact that there were about a dozen reddened nodules on the sides of his feet about the size of a large pea, some being larger. These were tender. What were they? Also should calluses on heels be removed surgically? After he had been a few weeks off his feet, the nodules disappeared. There were also cramps of the calves of legs extending to a short distance below the knees. This condition is still present and has existed over a period of three months.

C. L. Percy, M.D., Salem, W. Va.

ANSWER.—This patient's history is typical of strain of the feet. In such cases pain in the foot frequently is in the region of the navicular and talus articulation, although pain in the heel is not infrequent, particularly at the point where the plantar aponeurosis attaches into the calcaneus. The muscle spasm in the calves of the legs is a symptom of foot strain and muscular insufficiency. The pea sized nodules as described are seen in cases of foot strain and are due to inflammatory reaction in the subcutaneous tissue. The inflammation subsides with rest. Hot packs and rest will help relieve the muscle spasm in the legs. The calluses on the heels are usually due to faulty weight bearing, which, with a history of foot strain, suggests the presence of a pes valgoplanus. The calluses should not be removed surgically. They will disappear if the cause is removed and would recur even if removed surgically unless the underlying causative factors were cured.

Elevation of the feet with hot packs and rest allays the acute symptoms. The decompensation can be combated by means of adhesive strapping with the heel in varus and the anterior part of the foot in pronation. Correction can be maintained by means of corrective shoes. The heel should be held in varus by raising the inner side of the heel of the shoe, and the anterior part of the foot should be brought into pronation. This can be accomplished by means of the comma shaped bar.

Hauser, E. D. W.: Diseases of the Foot, Philadelphia and London, W. B. Saunders Company, 1939, chapter on Pes Valgoplanus.

TERTIARY SYPHILIS

To the Editor:—A Negro aged 35 presented himself in the office two months ago with four typical gummatous ulcers on his left leg and foot. The Hinton test was positive. The patient was mentally and physically well developed. His pupils were equal and reacted well. The teeth were normal. There was no evidence of disease of any internal organ. The ulcers, which had been existing for five months (the patient had been treated under an erroneous diagnosis elsewhere), healed within two weeks under preparations of bismuth and iodine and local application of mercury ointment. Neosphenamine, however, is poorly tolerated (diarrhea). I wonder how long treatment should be continued, as many authorities say that no cure can be achieved in the third stage of this type. An interesting aspect is the patient's father, who is white except for Addison-like spots on the cheeks and has typical Negroid features. The man asserts that he had the ordinary Negro color until about seven years ago, when he was stricken with a severe disease connected with high fever. It is to this disease that he ascribes the loss of his color. This seems highly improbable to me but the man is intelligent and educated, and, on the other hand, I do not have much experience with Negroes. I would appreciate your opinion as to both questions.

M.D., Massachusetts.

ANSWER.—No information is furnished on this patient as to a careful check-up of the central nervous system, including a lumbar puncture. Moreover, because of the frequency of cardiovascular syphilis in a Negro it would be well to have the heart gone over carefully not only from the standpoint of physical examination but also radiographically. It is unwise in such a late case of syphilis to employ arsenical therapy in the beginning. It would be much better to keep the patient on bismuth therapy and potassium iodide for at least twelve weeks, giving intramuscular injection of bismuth subsalicylate 1 cc. in the alternate buttocks until he has had twelve of them. Then one might try an arsenical cautiously, provided there is no involvement of the cardiovascular apparatus, starting him off with a

small dose of mapharsen, e. g. 10 mg. intravenously, and if he stands it all right gradually increasing it up to a maximum dose of 60 mg., giving the injections once a week for a series of ten injections. Thereafter, if he stands the therapy well, one may alternate the bismuth injections and the arsenical injections until he has had thirty of each. In the succeeding year he may have two courses of bismuth with a rest period. Naturally, in the beginning no rest periods are allowed. With this type of syphilis it probably would be well to give potassium iodide in 0.5 Gm. doses before meals along with the bismuth therapy.

The therapy that is outlined is given on the premise that the patient does not have central nervous system syphilis. Naturally, if the patient has central nervous system syphilis other forms of therapy would be suggested, depending on the findings.

It is judged from the description that the patient's father has vitiligo, which is not an uncommon disease in the Negro. Of course, it has nothing to do with syphilis.

PROBABLE ATYPICAL LYMPHOCYTIC CHORIOMENINGITIS

To the Editor:—A man aged 34 noticed soreness about the back, abdomen and thighs about a month ago. He had some hoarseness of the throat but no fever. He was given respiratory vaccine on the assumption that he was coming down with a cold. The next morning he had a headache of moderate intensity which seemed to center over the left eye. It was accompanied by mild waves of nausea. The skin soreness progressed but there was still no fever. He was given more respiratory vaccine and nasal pack in an effort to get the sinus draining. The headache persisted three days, during which time a moderate amount of clear thick drainage was apparent in the back of the throat. The third day his temperature rose to 99.4 F. By this time the back was getting stiff. Six days after onset the patient noticed that the soles of his feet were numb. This numbness extended part way to the knees. The next day an acute urinary retention developed. A neurologist was called in consultation. The cranial nerves were normal; muscle tone was good; the abdominal reflexes and the right cremasteric were absent; the knee and ankle jerks were hyperactive. The Babinski sign appeared fleetingly on the right side and was gone the next day. There was no ataxia. Vibratory and touch sense were not impaired. The patient was well able to distinguish cold over the entire area involved but he could not distinguish heat on the left or legs up to the thighs. Lumbar puncture was done ten days after onset and there was no increase of pressure. The Queckenstedt test gave a normal response. In the spinal fluid there were 106 white cells, 88 per cent lymphocytes, 12 per cent polymorphonuclears and protein 56 mg. The colloidal gold curve was flat. The Kahn reaction was negative. Culture of the spinal fluid revealed no disease. The blood pressure was normal. There was no evidence of any other active disease. Please give probable diagnosis, prognosis and treatment. G. W. Brown, M.D., Buchanan, Mich.

ANSWER.—The history up to the time of the lumbar puncture, a period of ten days after the onset of the illness, indicates that the patient was suffering from a subacute infectious disease, most of the symptoms being referable to the central nervous system. The symptoms pointed to involvement of the meninges, the spinal cord and possibly the peripheral nerves, the cerebrum escaping. Many of the symptoms were mild, of a fleeting character and indicated a diffuse or widespread disease. The onset, the course and the symptoms were all characteristic of an invasion of the central nervous system by a neurotropic virus, beginning as a mild infection of the upper respiratory tract with general soreness of the muscles, hoarseness, mild headache, nausea, stiffness of the back and a slight elevation of temperature above normal. These signs were consistent with a type of virus infection known as acute lymphocytic choriomeningitis. The subsequent symptoms, however, would not be considered as typical findings in that disease, for urinary retention, sensory changes in the feet and legs and increased deep reflexes with the Babinski phenomenon point to a lesion of the spinal cord rather than to a disease primarily meningeal in type.

In acute lymphocytic choriomeningitis most of the symptoms can be accounted for on the basis of the meningeal involvement. Cases, however, have been known, and a few have been reported in the literature, indicating that the virus may be somewhat widespread in its action and that the other parts of the nervous system are occasionally involved. In 1 case, the report of which has not yet been published, there were in succession, although occasionally with some overlapping, four primary systems involved: retrobulbar neuritis of the optic nerves, meningitis with encephalitis, transverse myelitis of the spinal cord and peripheral neuritis. Signs and symptoms of all these individual variations were present at one time or another; no syndrome can be considered as exclusively the product of one of the neurotropic viruses.

The findings in the cerebrospinal fluid, moreover, bear out this point. The increased cell count is indicative of a meningeal reaction. The protein, being twice normal, suggests a deeper involvement of the nervous system. When the disease was first reported in adults in this country, by Viets and Watts (*The Journal*, Nov. 16, 1929, p. 1553) it was thought that polymorphonuclear cells in the cerebrospinal fluid were never enormous.

tered. Subsequently the same authors withdrew this opinion, for further study of additional cases (*J. Nerv. & Ment. Dis.* 80:253 [Sept.] 1934) indicated that polymorphonuclear cells, particularly in the first few days of the disease, were not by any means a rarity. The changes, therefore, in the cerebrospinal fluid on the tenth day of this patient's illness would be considered consistent with a diagnosis of acute lymphocytic choriomeningitis. It should be pointed out, however, that except for the negative Kahn reaction the changes in the cerebrospinal fluid would also be consistent with neurosyphilis of the meningeal type. If one should add, moreover, a positive Pandy reaction or find increased globulin in the cerebrospinal fluid by the ammonium sulfate test, the diagnosis of neurosyphilis would be much more certain.

In recent years, valuable new laboratory procedures have been developed for the diagnosis and differentiation of neurotropic virus diseases. Tests are now available on the blood serum for lymphocytic choriomeningitis as well as for various types of encephalitis and poliomyelitis (Laboratory Aids in the Diagnosis of Neurotropic Virus Diseases, Circular Letter 107, Oct. 22, 1941, War Department, Office of the Surgeon General, Washington, D. C.). Examination may also be made of specimens of the nervous system if these become available. For lymphocytic choriomeningitis there are complement fixation and neutralization tests on the blood serum as well as virus studies, which serve to identify the disease.

The prognosis of acute lymphocytic choriomeningitis is good. No death has been reported in an unmistakable case since the identification of the virus by Armstrong (*Pub. Health Rep.* 49:1019 [Aug. 31] 1934). Viets and Warren (*THE JOURNAL*, Jan. 30, 1937, p. 357) reported pathologic observations in a case in which death occurred before the virus identification was known, but this case cannot be considered, in the light of subsequent knowledge, as authentic although the clinical manifestations were suggestive of the disease.

There is no specific treatment. Most patients, however, recover without residual manifestations. The disease may be extremely severe and the outlook for life often appears to be grave during the height of the illness. Most cases, however, are of a mild nature and many probably pass unnoticed or are classified as mild respiratory infections similar to the situation found in other diseases caused by neurotropic viruses such as poliomyelitis. In the present case, because of the myelitis, the prognosis should be somewhat more guarded than in the more typical cases of acute lymphocytic meningitis.

SMALL AIR CONDITIONING UNIT

To the Editor:—Have you any information regarding the installation of a desirable type of air conditioning unit in an operative surgery? Or, necessarily, this cannot be a built-in unit but must be one to set in or on a portable type, as the operating rooms are already built.

R. J. Rorer, M.D., Kakamo, Ind.

ANSWER:—A desirable air conditioning unit for an operative surgery should maintain a maximum temperature of 80 F. with 60 per cent relative humidity when the outside temperature is zero and a minimum of 75 F. with the same humidity when the outside dry bulb is 95 and the wet bulb is 76. These conditions should be maintained with an outside air supply of eight air changes per hour. The unit should have replaceable air filters and means for recirculating air in order to obtain the desired air conditions quickly for emergency operations. It is important that recirculation be shut off completely before the patient is brought into the ward.

A "self-contained," "year-round" room conditioner of this sort is bulky and requires connection to steam, water, drain and electricity. It is usually placed under a window and connected to the outside through the lower part of the window. A spark-proof thermostat and humidistat must be furnished.

A straight-room cooler ("summer air conditioner") is much simpler and can be truly portable, but it lacks the essential feature of humidification and has no provision for warming the outside air supplied in cold weather.

A separate exhaust system is necessary, having a capacity equal to that of the supply system and exhausting the used air, preferably through an adjoining sterilizing room. The exhaust grille may be connected to an existing hospital exhaust, or a propeller exhaust fan may be built into an outside wall, or attached to the upper part of a window. The propeller fan should be equipped with automatic shutters.

The chief disadvantage of self-contained room conditioners is their noise. It would help a great deal if the refrigerating compressor was installed outside the room and the refrigerant piped to the room unit. If several operating rooms are to be conditioned, a central station plant installed in the basement is definitely advantageous.

ATYPICAL MYASTHENIA GRAVIS

To the Editor:—A girl aged 17 years began four years ago to have weakness in her muscles. She swayed on walking, and her arms tired easily. After a ten months rest in bed her strength returned and she was active until January 1940. Then she had the grip, followed in February 1941 by scarlet fever. Since then she has been confined to bed with a return of her previous symptoms of weakness of both legs and arms. Till the onset of these attacks she was in good health. There is no history of muscular weakness in her mother's or father's family. She has three younger siblings, all normal. From February to July her condition remained stationary. She did get out of bed to sit in a chair for half an hour a day, only to return because of being extremely fatigued. In July 1941 she began having a hacking cough. This began in late afternoon. The cough was not relieved by opiates or usual cough syrups. The palate was not long. The only relief was obtained by having her roll over on her stomach. By early morning she could roll over on her back again without coughing, only to begin coughing again in the late afternoon. The hour at which the cough begins has been constant, except that lately it has been somewhat earlier. Coincidentally with the development of the cough she began having an afternoon rise in temperature up to 100.5 F. by mouth. Following the removal of two infected teeth, the temperature returned to normal. A month ago a prostigmine methylsulfate test was negative. That evening she had cramps in the abdomen. Since then she has gagged and had abdominal cramps and fibrillary twitchings of arms and legs. For the past two weeks she has had herpes zoster on her legs, spreading to the trunk and arms. The general skeletal development is good; the muscles are somewhat small; the pulse varies from 80 to 100; the blood pressure is 114 systolic, 70 diastolic. The isthmus of the thyroid gland is palpable. The knee jerks are present but diminished. The Babinski reflex is negative. There are no gross sensory changes. I have considered this to be a case of progressive muscular dystrophy. Is this consistent with the course described? She has had wheat germ oil, 10 drops daily, for two months. A sedative prevents her gagging attacks. What would be the cause of the coughing? Is it usual for patients with dystrophy to have these attacks? What is the prognosis? M.D., New York.

ANSWER:—The patient has in all probability atypical myasthenia gravis (Erb-Goldflam's disease, or pseudobulbar asthenia). Progressive muscular dystrophy produces objective evidence of organic muscular disease such as hypertrophy or atrophy. The cause of the coughing is probable involvement of the chest and throat muscles. It is not common for patients with dystrophy to have attacks of coughing. Myasthenia gravis is a serious ailment and is incurable. The following may be suggested: Give 2 cc. of 1:2,000 solution of prostigmine methylsulfate by hypodermic injection and watch for improvement. This should occur in ten to thirty minutes. Following this one should test a muscle with a faradic current at 75 per cent interruption. After this has been done the tested muscle will cease to react. After a few minutes rest the tested muscle will react again. If these tests are positive, the patient may be placed on either of the following regimens: Ephedrine hydrochloride $\frac{3}{8}$ grain (0.024 Gm.) three times daily with prostigmine bromide (15 mg. tablets three times daily) by mouth. Instead of the ephedrine or prostigmine one may give guanidine hydrochloride in doses of 15 to 30 mg. per kilogram of body weight daily.

PREGNANCY FROM COITUS DURING MENSTRUATION

To the Editor:—The question of whether a woman could become pregnant during her menstrual period has arisen. Manwaring of Stanford reports the discharge as "lethally toxic for normal mature rats." Would not the same effect be applicable to normal sperm?

George K. Herzog, M.D., San Francisco.

ANSWER:—The common aversion to coitus during menstruation is probably based on esthetic reasons rather than on any scientifically demonstrable harmfulness to either partner. There appears to be little evidence as to the effect of the menstrual discharge on the motility or potency of spermatozoa. The well known dictum of Ambroise Paré that coitus during menstruation breeds monsters belongs in the realm of superstition. Gynecologists are inclined to attach less importance than they formerly did to the detrimental influence of cervical and vaginal discharges on the spermatozoa. While it seems theoretically possible that the menstrual discharge would exert an inimical effect, this factor alone could not be considered to exclude absolutely the possibility of impregnation during the period.

Much more important would seem to be the fact that there does not appear to be unimpeachable evidence that ovulation occurs during menstrual periods of normal duration. Regardless of what one may believe as to the value of the so-called safe period in biologic contraception, the evidence indicates that ovulation does not occur sometime within a definite though rather long "ovulation span." This embraces many days, but there does not appear to be definite proof that it has occurred earlier than the eighth day of the cycle, which places it beyond a menstrual period of average duration. The reader may be referred to Hartman's work on "The Time of Ovulation in

Women" for a further discussion of this point. The incompleteness of knowledge on this subject does not justify dogmatic statements, but it seems exceedingly unlikely that coitus during menstruation would be productive.

TONSILLECTOMY IN ALLERGIC OR HAY FEVER PATIENTS

To the Editor—Am I correct in assuming that it is wise to defer until after the hay fever season (ragweed season) the removal of tonsils and adenoids in a child who either is allergic or has a definite family history of allergy? Is there any proof that in patients with a family history of allergy or an allergy themselves definite allergic manifestations develop or become worse after tonsillectomy during the hay fever season, and, if so, what is the explanation or basis for the appearance or exacerbation of the allergy?

Meade Edmunds, M.D., Petersburg, Va.

ANSWER.—Specialists in the field of allergy almost without exception strongly oppose the removal of tonsils and adenoids in a hay fever sufferer during the hay fever season. This is because the tissues are apt to be swollen from the hay fever; secondary infection is more likely to occur because of decreased resistance. Sneezing and coughing increase the danger of post-operative hemorrhage.

Tuft (Clinical Allergy, Philadelphia, W. B. Saunders Company, 1937, p. 373) states: "The relationship of operations on the nose or throat, such as submucous resection or tonsillectomy, to the production of the initial attack of hay fever is difficult to evaluate. The reported instances of hay fever beginning shortly after surgery of this type are too numerous to be coincidental and emphasize the necessity for caution in performing operations on children of allergic parents."

In children who are allergic or whose parents are allergic, cutaneous tests for pollens should be done before any operation on the nose or throat, especially if surgical intervention is contemplated during the three pollen seasons (March to October).

INTRAUTERINE KERATITIS OR BIRTH INJURY OF CORNEA

To the Editor—A white boy aged 2 weeks, whose mother is a primipara was delivered by high forceps. I see no evidence of a direct injury to his eyes. The right cornea is clouded to the extent of making an intra-ocular inspection impossible. The pupil is barely discernible but seems to react normally to light. The anterior chamber is of proper depth. The eyes are of equal and of normal size. There is no evidence of an infection in the cul-de-sac, iritis or conjunctivitis. The blood Wassermann reaction of both parents and of the baby are negative. Intra-ocular tension is within normal limits. The baby is "normal" in other respects. There is no history of similar mishap in either side of family. I am wondering whether ethylmorphine hydrochloride is safe to use. Could this drug used as drops in the eye cause a possible addiction to morphine? Is there a known treatment that might give a brighter prognosis?

James Hicks, M.D., Brunswick, Ga

ANSWER.—The cloudy cornea may be the result of an intra-uterine keratitis, with or without uveitis, of a birth injury to the cornea or of a keratitis subsequent to birth. In many such instances the corneal opacity clears within the course of six months without treatment. As far as is known, there is no definite treatment that will hasten the process. Ethylmorphine hydrochloride may be used, but present evidence tends to disprove any such definite therapeutic effect of that drug. There is no danger of producing an addiction to morphine by the instillation of ethylmorphine hydrochloride into the conjunctival sac.

MILD GASTROINTESTINAL EPIDEMIC

To the Editor—What are the possible diagnoses in an "epidemic" seen in New York City between Nov. 28 and Dec 9, 1941, and still going on? In many families throughout the city one or two members were stricken with nausea, vomiting, abdominal cramps and borborygmus, followed in twelve to twenty-four hours by a foul smelling diarrhea lasting two or three days. There were neither chills nor fever nor especial weakness. In milder cases only a day's siege of diarrhea would occur. New cases in the family might follow in two days, occasionally three or four, after the first case. In most cases the children were affected first, then their parents. I recall similar outbreaks in past years in the late fall when there was no influenza prevalent. Has a virus gastroenteritis without fever ever been reported?

M.D., New York

ANSWER.—It has been observed that during epidemics of influenza, even of the milder types, gastrointestinal symptoms may dominate the clinical picture. As a rule some febrile reaction occurs, but in certain outbreaks fever has been only slight in many cases.

It would seem probable that the etiologic agent in these disorders is a virus. However, the virus in the intestinal tract in these cases has not been demonstrated as far as a careful search of the literature has revealed.

Food poisoning might be responsible for symptoms similar to those observed, although fever is present in most food poisoning outbreaks. Other possible diagnoses are mild specific types of dysentery, which also usually produce some fever in those affected.

It would appear that further research in the epidemic observed in New York would be necessary to determine the exact category in which the disease belongs.

APPETITE AND THE CHILD

To the Editor—A boy aged 5 years has always been a "poor and picky" eater; in spite of this he is in good flesh and normal weight but does seem to catch cold rather easily. As an infant he always took his milk well, but when he began to eat solid foods he would not touch many of them. At present he will eat no meat whatever—"this since he learned where meats came from." Of vegetables he will eat only raw carrots, raw celery and potatoes. He will eat most cereals, on occasional egg, a few desserts, will take his milk freely, and he will take most fruits; but some must be cooked or he will not take them. What would you advise my recommending to the parents?

Raymond H. McPherron, M.D., Chicago

ANSWER.—The parents should be informed that if the child is in good physical condition as stated there is nothing to worry about in his present diet. It covers all the necessary food elements. If this attitude is adopted and no further attention is paid to his eating habits, he will eventually broaden his diet himself. Nursery schools where children are given meals together help in this. A good book for the parents to read is C. A. Aldrich's "Cultivating the Child's Appetite."

TULAREMIA FROM WILD AND TAME RABBITS

To the Editor—During the past ten years I have seen about 18 cases of tularemia which could be traced directly to having cleaned wild rabbits, commonly known as jack rabbits in the Western states. Please let me know if tularemia ever occurs in tame rabbits or in the species of wild rabbits, also found in the Western states, which are known as the cottontail?

A. L. Graff, M.D., Cedar City, Utah

ANSWER.—The wild cottontail rabbit is the most important host and transmitter of tularemia east of the Mississippi River. In the Western states the jack rabbit, cottontail and snowshoe rabbits are the principal animal hosts. There are no authenticated records of tularemia acquired from contact with domesticated rabbits. Rabbits raised under domestic conditions, although highly susceptible, have not been found naturally infected, probably owing to their freedom from the ticks which commonly infest wild rabbits.

IMMUNIZATIONS FOR EUROPEAN WORK

To the Editor—I have under my care two young men who intend to go to Europe to do war relief work. I wish to immunize these men against typhus and cholera. Can you tell me where in the United States these immunizing agents can be obtained? Are there any immunizations other than typhoid, paratyphoid A and B, smallpox, typhus and cholera which you would recommend?

Lucille Carman, M.D., North Manchester, Ind

ANSWER.—Both typhus and cholera vaccine may be obtained from either the Eli Lilly Company or the Lederle Laboratories at Pearl River, N. Y.

Immunization against typhoid, paratyphoid A and B, smallpox, typhus and cholera protects against those diseases which are of greatest danger.

The efficacy of typhus vaccine in human beings has not been established, but its use is advised.

MIGRAINE, SICK HEADACHES AND FOOD ALLERGY

To the Editor—Approximately 70 per cent of cases of migraine and recurrent headaches are benefited or relieved by the exclusion of allergenic foods from the diet. It is unfortunate, therefore, that the adequate study of food allergy was not stressed in the answer to the query concerning atypical migraine in *The Journal*, July 5, 1941, page 78. Success has long been reported by various allergists with diets excluding foods to which cutaneous reactions or a history of definite idiosyncrasy or dislike occurs. For many years I have relieved the majority of these sufferers with elimination diets modified by a history of possible idiosyncrasies and definite cutaneous reactions by the scratch tests. Such diets should be used as diagnostic tools for the study of possible food allergy. Detailed menus for such diets together with a discussion of their use, necessary recipes and emphasis on the maintenance of nutrition have recently been published in "Elimination Diets and the Patient's Allergies," Philadelphia, Lea & Febiger, 1941. The cyclic recurrence of allergic headaches is usually due to refractoriness, which occurs after many allergic reactions. Anergy or the inability to react allergically explains the relief of allergic migraine during pregnancy, mentioned in the query. The disappearance of asthma and less commonly of other allergic manifestations during gestation is due to the same cause.

RATE OF HEMOGLOBIN REGENERATION IN BLOOD DONORS

WILLIS M. FOWLER, M.D.

AND

ADELAIDE P. BARER, Ph.D.

IOWA CITY

During the past twenty years there has been a great increase in the number of blood transfusions administered, and the recent use of normal and lyophilized serum in combating shock and in restoring the plasma proteins to their normal level promises to increase still further the already great demand for blood. In spite of the frequent use of whole blood and blood serum there have been surprisingly few studies on the rate of hemoglobin regeneration in the blood donors. Most of the recorded observations have been made on groups of professional donors who have given varying amounts of blood over a period of months or years, and the reports have been concerned with the hemoglobin and erythrocyte levels after multiple donations. Giffin and Haines¹ studied 84 donors, many of whom had given blood for 20 or more transfusions, and concluded that donations of 500 cc. of blood at intervals of four to five weeks are not harmful to male donors but that in female donors anemia often develops under similar conditions. Powell² studied 25 donors, 1 of whom had given blood for 63 transfusions, and found that anemia had developed in only 2 of the group. Jones, Widing and Nelson³ studied 50 donors who had given blood for a total of 175 transfusions and found that the blood hemoglobin level rapidly returned to normal. Certain donors exhibited such regenerative ability that the withdrawal of 1,200 to 2,000 cc. of blood within a period of one to twenty-three days was followed by a return of the hemoglobin level to normal within ten days. Martin and Myers⁴ found an average reduction of 310,000 in the erythrocyte count and a 5.2 per cent drop in the hemoglobin level following the removal of 500 cc. of blood. The minimum values were found six hours after the bleeding. No ill effects were noted in 10 donors who had given blood for a total of 52 transfusions, but Martin and Myers expressed the belief that blood should not be taken more frequently than every three

months. They too noted that hemoglobin regeneration is slower in female than in male donors. The same interval, three months, between blood donations was recommended by Brewer⁵ after observations on 1,076 donors, although he found that the hemoglobin had returned to its normal level at the end of two months in most donors. Cadham⁶ found that six months after the withdrawal of small amounts of blood for transfusions of convalescent serum there was no anemia and most of the subjects felt better than they had prior to the blood donations.

Less encouraging reports have been given by other investigators,⁷ who have found instances of persistent anemia after repeated donations of blood, and in some cases⁸ a reduction in the leukocyte count has been noted. A study of 101 Chinese donors⁹ revealed a reduction in the blood hemoglobin that paralleled the amount of blood withdrawn and the time that the subject had been serving as a blood donor. The anemia was of the microcytic type, and glossitis, achlorhydria and splenomegaly were occasionally encountered. The slower hemopoietic response in Chinese donors was attributed to the poor diet on which they subsisted, and it was found that they responded rapidly to the administration of an iron salt.

We have made observations on a total of 200 blood donors who have given blood for 636 transfusions at the University Hospitals. The list of donors was composed almost entirely of medical students, the resident staff and hospital employees, so that the subjects were predominantly young men who were available for follow-up study. A prerequisite to being placed on the list was the absence of organic disease detectable by physical examination, a negative Wassermann reaction and a blood hemoglobin level of 11.5 Gm. or more, except that in the early stages of the investigation a few donors with a lower hemoglobin reading were included. No blood was taken from a donor if a history of a recent infection or other illness was obtained.

An attempt was made to obtain the following data on each subject: the blood hemoglobin level immediately before the giving of blood, the level twenty-four hours after the donation and the level at weekly intervals thereafter until it had returned to the predonation value. In some instances the hemoglobin level prior to the donation was not determined; so the fall in the hemo-

RECEIVED FEBRUARY 10 1942
SECTION OF MEDICINE

globin level and the recovery time could not be ascertained, although the rate of hemoglobin regeneration could still be determined. It was necessary to drop some subjects for various reasons before their recovery was complete, and whenever an infection of the upper respiratory tract or another illness that might influence

Chart 1—Recovery period by weeks

hemoglobin regeneration intervened the subject was immediately dropped from the study. Some subjects reported irregularly for hemoglobin determinations rather than at the specified weekly intervals. For these reasons complete data are not available for all the subjects who were under observation.

The data on hemoglobin regeneration were studied in three ways: 1. The length of time between the blood donation and the return of the blood hemoglobin to its original level, called the recovery period, was determined. 2. The weekly increase in hemoglobin over the amount at the first postdonation reading was ascertained, and from this the average gain per week was determined. 3. The daily increase in hemoglobin per hundred cubic centimeters of blood was ascertained, even though the donor was not followed until complete recovery.

Hemoglobin determinations were made almost entirely with the Newcomer hemoglobinometer, although a photoelectric photometer was used for a few of the more recent subjects. Both instruments were checked by the oxygen capacity method of Van Slyke. Hematocrit determinations were made in duplicate at the time of each hemoglobin determination.

Chart 2.—Relationship between hemoglobin drop and recovery period

The blood for transfusion was drawn by members of the resident staff into 1,000 cc. graduated flasks in which had been placed a known amount of anticoagulant. The measurement of the amount of blood withdrawn was made from the graduations on the flask and was only grossly accurate. In a group of 155 donors the amount of blood withdrawn ranged from 475 to 600 cc., with an average of 555.7 cc.

In this group the levels of hemoglobin per hundred cubic centimeters of blood averaged 128 Gm., with a range of 15 to 10.5 Gm. With the withdrawal of 500 to 600 cc. of blood (the average was 555 cc.) there was a drop in the blood hemoglobin content which averaged 2.3 Gm. per hundred cubic centimeters, the greatest drop being 4.4 and the smallest 1.2 Gm. The 2.3 Gm. represents an average drop of 18 per cent, which is considerably greater than that reported by Martin and Myers.⁴

After the donors who were not followed until the hemoglobin level had returned to normal and those who did not have predonation hemoglobin readings done are excluded, there were 105 men whose recovery period was ascertained. The average time required for the blood hemoglobin to return to its original level was forty-nine and six-tenths days. There were wide variations among the individual recovery periods, the longest being ninety-eight days and the shortest eighteen. There were 29 donors whose hemoglobin had exceeded the original level by the time the first normal reading was obtained, so that the actual recovery period was slightly shorter than that recorded. The recovery period of nearly fifty days is considerably longer than that suggested by some of the previous reports. The number

Mean	0.54	0.83	1.20	1.46	1.66	1.76	1.83	2.05	1.79	2.01	2.42	1.75	2.36	2.23

Chart 3—Hemoglobin increase by weeks

of donors whose hemoglobin level returned to normal during each seven day period is shown in chart 1. It will be noted that the hemoglobin of 1 donor returned to the original level during the third week, of 6 during the fourth week, of 16 during the fifth week and of 17 to 20 during each of the sixth, seventh and eighth weeks, so that the majority (74.2 per cent of the 105 subjects) had recovered at the end of this period. However, 25.8 per cent had not recovered at the end of eight weeks, whereas it is a common practice to have subsequent blood donations taken after an interval of only six to eight weeks.

From each of 30 donors 250 to 300 cc. of blood was withdrawn on each of two consecutive days, the second donation being taken twenty-four to thirty hours after the first and the reading to determine the fall in the blood hemoglobin being made twenty-four hours after the second donation. The average amount of blood withdrawn from these 30 subjects was 575 cc., and the average drop of the hemoglobin content was 2.2 Gm. The average recovery period for 26 donors, on whom the data was complete, was forty-five and four tenths days, with a range of twenty-seven to seventy-three days. This average is not significantly less than the average of forty-nine and six-tenths days for the entire group of men who gave the same amount of blood in a single donation.

It is well recognized that the rate of hemoglobin regeneration varies from one person to another; so it is

not surprising to find wide variations in the recovery periods. Because of the inaccuracies in measuring the amount of blood withdrawn for transfusion, an attempt was made to correlate the recovery period not with the amount of blood lost but rather with the fall in the blood hemoglobin level. No direct correlation could be made in individual cases, since, for example, the subject with the longest recovery period (ninety-eight days) had a drop in hemoglobin of 2.1 Gm., whereas the subject with the shortest recovery period (eighteen days) had a drop of 2.2 Gm. In general, however, the shortest recovery periods were those of the donors who showed the least drop in hemoglobin and the longest recovery periods those of the donors who showed the greatest fall in hemoglobin. For 23 donors whose recovery period was thirty-five days or less the average fall in hemoglobin was 2 Gm., while for 21 whose recovery period was sixty-three days or more the average fall was 2.7 Gm. From the foregoing statements it may be seen that the donors with a shorter

donors giving larger amounts of blood. The fall in the blood hemoglobin content in this group varied from 1.7 to 0.6 Gm., with an average of 1.2 Gm. Only 7 of these 11 donors were followed until complete recovery, and their recovery period varied from twelve to sixty-five days, with an average of thirty-three and three-

tenths days, which is significantly shorter than the average for the group who donated larger amounts of blood and showed a greater fall in hemoglobin.

The donors were predominantly men; so data were obtained on only 13 female donors. Their average drop in hemoglobin content was 2.2 Gm., and for the 5 who were followed to complete recovery the period ranged from thirty to seventy-three days, with an average of fifty-two and two-tenths days. This is but slightly greater than the average of forty-nine and six-tenths days for the entire group of 105 men whose recovery period was ascertained, but these data are not of great significance in view of the small number of cases. Of more significance is the average daily increase in hemoglobin for the 13 female subjects, 0.04 Gm. per hundred cubic centimeters, as compared with the 0.049 Gm. daily increase for the 155 men, suggesting that hemoglobin formation is slightly less rapid in women. Other investigators have reported that females are more prone to the development of anemia after repeated blood loss than are males and that they recover more slowly.

In order to determine the rate of hemoglobin regeneration in our donors—normal persons—we have grouped together all those who gave 500 to 600 cc. of blood. The recovery periods have been divided into weekly intervals, the gain in hemoglobin content over the content at the first postdonation reading has been recorded for each subject and the average gain for the entire group at the end of each week has been determined.

Since observations were discontinued when the hemoglobin reached the original level and because some subjects dropped from observation, there is a gradual reduction in the number of donors for whom the averages were determined after the first five weeks. This gain in hemoglobin per week, together with the number of donors from whom the averages were derived and the curve of regeneration, is portrayed graphically in chart 3. It will be noted that there is an average increase of 0.54 Gm. during the first two weeks and a

Chart 4.—Hemoglobin regeneration after repeated donations.

recovery period had the smaller reduction and those with a longer recovery period the greater reduction in hemoglobin. Sixteen subjects' blood hemoglobin content dropped 2.8 Gm. or more after the blood donation. The average drop for the 16 was 3.2 Gm. and the average recovery period sixty-one and two-tenths days. For 26 subjects whose drop was 1.9 Gm. or less the average drop was 1.6 Gm. and the average recovery period was forty-three and one-tenth days. It is evident from these data that the subjects with the greatest fall in the hemoglobin level had a longer average recovery period (sixty-one and two-tenths days) than did those with a smaller drop (forty-three and one-tenth days). In chart 2 the recovery period in days is plotted against the fall in hemoglobin, and it may be seen that in spite of individual variations in the rate of hemoglobin formation there is a linear relationship between the two and that the period necessary for recovery corresponds in general to the fall in hemoglobin.

From each of 11 donors only 300 cc. of blood was withdrawn, and they have not been included with the

subsequent gain of approximately 0.2 to 0.3 Gm. each week for the subsequent ten weeks. After the tenth week the curve is more irregular. Since the subjects followed for the longest time are those with the slowest hemoglobin regeneration and since those whose blood hemoglobin level had returned to normal were dropped from this study, the increase in hemoglobin in the later periods is less rapid.

The daily gain in hemoglobin per hundred cubic centimeters of blood was determined for each subject, and it was found that the average daily gain for the entire group of men was 0.049 Gm., with a standard deviation from the mean of ± 0.023 Gm. These data

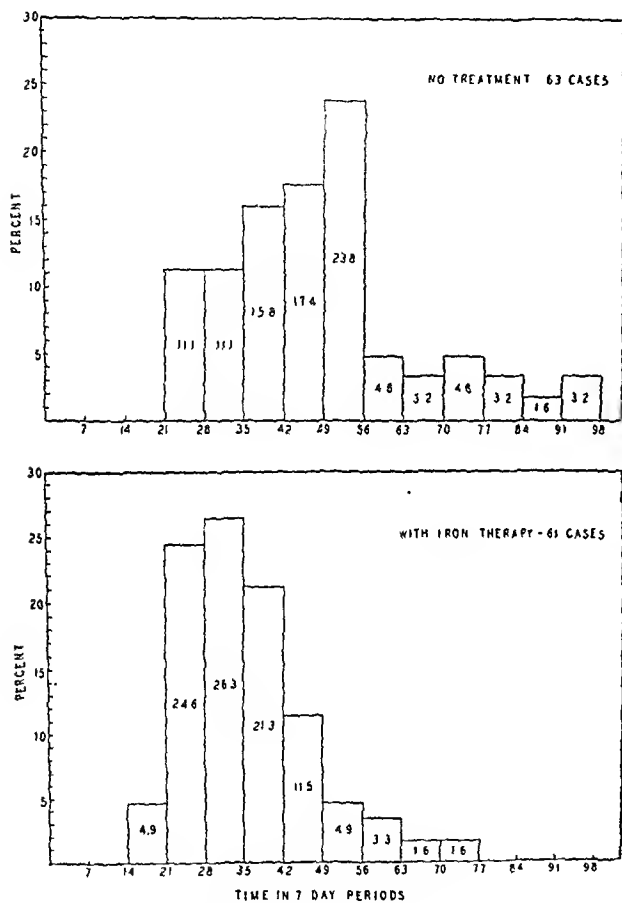

Chart 5.—Recovery period with and without iron therapy.

show the rate of hemoglobin regeneration in normal persons following the loss of a known amount of blood. No medication of any type was allowed.

In an attempt to ascertain whether or not the original blood hemoglobin level had any effect on the rapidity of regeneration the average daily increase was determined for donors whose hemoglobin level was 13.5 Gm. or more and for those whose level was 12.5 Gm. or less. For donors with the higher hemoglobin levels the average daily increase was 0.048 Gm., while it was 0.055 Gm. for those with the lower readings. It is apparent therefore that the initial hemoglobin level is not a significant factor in the rapidity of regeneration.

Twenty-one subjects were followed after a second blood donation. Their average hemoglobin drop after the first donation was 2.1 Gm., and their average recovery period was forty-three days. The average drop after the second donation was 2.3 Gm., and the average recovery period was fifty-two and one-half days.

This seems to indicate a lengthening of the recovery period, but in table 1, in which are given the individual records of the 7 subjects (of the 21) on whose recovery period after each donation the data were complete, it may be seen that for 4 donors (donors 1, 2, 3 and 5)

TABLE 3.—Recovery Period and Hemoglobin Gain After Two Donations, With and Without Iron Therapy

it was longer and for 3 it was shorter after the second donation. For the 2 donors whose hemoglobin drop was almost identical after the two donations (donors 4 and 6) the recovery period was shorter after the second. Two donors gave 4 donations, and their recovery periods and the changes in their hemoglobin content are given in table 2. For donor 1 the recovery period was shorter after the third and fourth donations than after the first, and for donor 2 the period was shorter after the second but longer after the third donation. In chart 4 are plotted the hemoglobin gains per week in donors who gave more than 1 donation. In part 1 are the curves for the 21 donors after their first and second donations. In part 2 the average gain is shown for 4 subjects after each of 3 donations and in part 3 the average hemoglobin gain for 2 subjects after each of 4 donations. It is to be noted that there was no appreciable decrease in the rate of hemoglobin regeneration after 4 donations had been given. This is also evident from the average daily hemoglobin increase, which for 21 subjects after the first donation was 0.046 Gm., whereas after the second donation it was 0.048 Gm. The average daily hemoglobin increase for 4 subjects after their third donation was 0.051 Gm., and for 2 subjects after their fourth donation it was 0.06 Gm., so that in none of these subjects was the rate of regeneration slower after subsequent donations than after the first. All the subjects were followed until the original hemoglobin level was reached, and the next donation was given from one to seven days later. The interval between donations varied slightly, but subsequent donations followed soon after the subject's hemoglobin level had returned to normal.

EFFECT OF IRON THERAPY ON HEMOGLOBIN REGENERATION

Although the donors were receiving a normal diet and there was no evidence of or reason to suspect any degree of iron deficiency, we gave 1 Gm. (15 grains) of iron and ammonium citrates daily to certain subjects to study the effect on their hemoglobin regeneration. Eighty-nine donors gave one donation of blood

without medication during the recovery period and received iron and ammonium citrates after a second donation. The average daily hemoglobin gain for these 89 subjects after the first donation was 0.0518 Gm., and the average recovery period was forty-eight and two-tenths days for the 63 donors for whom it could be determined. After the second blood donation, with iron therapy, the average daily hemoglobin gain was 0.0772 Gm., an increase of 49 per cent over the gain in the first period. The average recovery period was only thirty-five and two-tenths days, a drop of thirteen days, or 26.9 per cent.

Of the 89 donors studied after each of 2 donations the recovery period of 63 was determined after the first donation and of 61 after the second. In chart 5 is presented the percentage of each group whose hemoglobin level returned to normal in each seven day period. The upper part shows the percentage of donors whose level returned to normal each week after the first donation, when no medication was administered, and the lower part shows the results in the period after the second donation, during which the subjects were receiving iron therapy. The upper part corresponds in general to the results shown in chart 1 for 105 subjects.

the period following the second donation, during which iron was administered. It will be noted that the hemoglobin increase was definitely more rapid when iron was given and that the hemoglobin had returned to its original level by the end of the eleventh week in all subjects.

These data have shown a definite increase in the rate of hemoglobin regeneration and a shortening of the recovery period during the administration of iron after a second blood donation. In a smaller group, of 15 subjects, iron was administered after the first blood donation and withheld after the second. In table 3 are shown the results for this group. After the first donation the average recovery period was thirty-nine and one-tenth days and the average daily hemoglobin gain was 0.0675 Gm. After the second donation, when no iron was administered, the average recovery period was definitely prolonged and averaged fifty-two and six-tenths days. Of greater significance is the daily hemoglobin gain of 0.0426 Gm., which is a decrease of 36.8 per cent from the previous rate of increase. It will be noted that, whereas the administration of iron after the second donation increased the rate of hemoglobin formation by 49 per cent, the withholding of iron

11	2.17	39.6	0.0547	2.45	28.4	0.1010	2.55		0.0711	2.41	48.4	0.0489	2.67	45.3	0.0579

None had a recovery period of less than twenty-one days, but 11.1 per cent recovered during each of the fourth and fifth weeks. During the next three weeks there was a gradual increase, with a peak of 23.8 per cent recovering during the eighth week. After this there was a sharp drop, so that from 1.6 per cent to 4.8 per cent of the donors recovered each week for the next six weeks. The results obtained after the second donation, during which period iron was administered, are in sharp contrast to those obtained after the first donation. In 4.9 per cent of the donors the hemoglobin level returned to normal during the third week, as compared to no returns to normal the third week in the previous group, and during each of the next three weeks 24.6, 26.3 and 21.3 per cent recovered. Of the donors not receiving iron the level in 78.2 per cent had returned to normal by the end of the eighth week, whereas of those receiving iron 77.1 per cent had recovered by the end of the sixth week and 93.5 per cent by the end of the eighth week. Chart 5 illustrates graphically the drastic reduction in the recovery period produced by iron therapy.

The effect of iron is further emphasized in chart 6, in which is plotted the average hemoglobin gain each week for the entire group of 89 subjects after each of the two blood donations. The lower, solid line shows the average weekly gain after the first donation, when no iron was administered. There was a steady increase during the first nine weeks and then a more irregular and a slower increase as fewer donors remained for study. The upper line shows the hemoglobin gain in

during the second postdonation period when it had been given during the first period lessened the rate of regeneration by 36.8 per cent.

The administration of iron also increased the rapidity with which the hematocrit reading returned to normal. In 108 subjects who received no iron the average time required for the hematocrit reading to return to its original level was twenty-nine and seven-tenths days, as compared with forty-nine and six-tenths

Chart 6.—Hemoglobin increase by weeks, with and without iron therapy.

days for the hemoglobin level. The recovery period ranged from nine to ninety-five days. With the administration of iron and ammonium citrates the average recovery period dropped to twenty-two and two-tenths days, individual periods ranging from eight to forty-nine days, which is a decrease of 25.2 per cent. The effect of iron on the hematocrit reading was less noticeable than the effect on hemoglobin regeneration but definitely hastened its return to normal

Six female donors were observed during iron therapy after a second blood donation, and the data on them are given in table 4. After the first blood donation, without therapy, the recovery period was fifty-two and four-tenths days and the daily hemoglobin gain was 0.0427 Gm. After the second donation, with iron therapy, the recovery period was forty-three and six-tenths days and the daily hemoglobin gain was 0.0629 Gm., an increase of 47 per cent over the gain in the first period.

The data so far presented have been concerned with only 2 blood donations and with the giving of iron during the second period. The iron therapy has uniformly increased the rate of hemoglobin formation. Some of the subjects have been studied through a series of blood donations during which they have received iron therapy continuously. Subsequent donations were given within a few days after the hemoglobin had returned to its original level. In table 5 are the data on these donors, all of whom were men who gave from 500 to 600 cc. of blood each time. The drop in hemoglobin, the recovery period in days and the daily hemoglobin increase are given for each group of subjects for each blood donation. The results following the first two donations have been discussed. It will be noted that after the third blood donation the recovery period was shorter and the hemoglobin regeneration more rapid than they had been after the first donation but that recovery was less rapid than after the second donation. After the fourth donation the rate of regeneration was still slower and was no more rapid than it had been during the first recovery period, in which iron therapy had not been given. In the 11 subjects followed through the fifth donation there was a slight gain in rate over that in the fourth period, but the rate was approximately that of the first period. From these data it is evident that the administration of iron had progressively less effect on hemoglobin regeneration but that the rate of regeneration did not drop below that which was noted after the first donation even though 5 donations were made in rather rapid succession.

SUMMARY

These data have been presented to show the drop in hemoglobin that occurs in healthy blood donors after the withdrawal of blood for transfusion and the time required for these persons to regain their normal hemoglobin level. In the event that it becomes necessary to set up transfusion services on a large scale such detailed information may be of value in the selection of donors and in determining the frequency with which they should be used, as well as in presenting accurate data to prospective donors as to the time which must elapse before their blood returns to normal. The average drop in hemoglobin, of 2.3 Gm., after a donation of 555 cc. of blood is not sufficient to be of danger or to produce more than transient symptoms. Although wide variations in the recovery period were noted among individual donors, there was a definite correlation between the drop in hemoglobin and the length of the recovery period in days. It was found that the average man regained the lost hemoglobin within fifty days without any form of therapy. With the donation of a smaller amount of blood and a consequent smaller drop in hemoglobin the recovery period was shorter. Persons with a higher initial hemoglobin reading did not regenerate hemoglobin more rapidly than those with a lower, but still normal, hemoglobin value. We

could detect no means by which the rapidity of hemoglobin regeneration in any one person could be predicted beforehand.

Subsequent blood donations may be given with safety as soon as the hemoglobin has returned to its original level, regardless of the elapsed time. In the majority of donors an interval of two months will suffice for hemoglobin regeneration, but 25.8 per cent in our series required a longer period. For this reason it is not advisable to establish a routine interval of two months between donations unless the donor's fitness to give blood is established by hemoglobin determinations. We did not feel that the regeneration of hemoglobin became slower after multiple donations than it had been after the first.

The response of the normal hemopoietic system to the loss of a known amount of blood is of interest. With the resultant mild anemia an average of 0.04 Gm. of hemoglobin per hundred cubic centimeters of blood was produced each day until the deficit was replaced. This was accomplished without medication but with a normal dietary intake of iron.

The administration of small amounts of iron to the blood donors had a surprising effect on hemoglobin regeneration. The rate of regeneration was increased nearly 50 per cent by the use of iron and there was a drastic shortening of the recovery period, so that subsequent blood donations were possible after a much shorter interval. With this medication the blood hemoglobin content in 93.5 per cent of the subjects had returned to normal by the end of eight weeks. The group of donors to whom iron was administered after the first donation but withheld after the second showed a slower hemoglobin regeneration during the second postdonation period. This shows that the increased rate of hemoglobin regeneration after the first donation was due to the effect of the medication itself rather than to a stimulation of the bone marrow from the blood loss. The effect of iron was transient, the donor being benefited only one or two recovery periods, so that continued administration of iron did not maintain the rate of hemoglobin regeneration above the original rate. There was no evidence of exhaustion of the bone marrow while the subjects were under observation, since the rate of hemoglobin regeneration after the fifth donation was approximately the same as that after the first.

The rate of hemoglobin regeneration was slightly less rapid in women than in men, and the time necessary for recovery was somewhat longer. The administration of iron during one recovery period increased the rate of hemoglobin regeneration 47 per cent. Because of the slower regenerative power of their blood female donors should be allowed longer intervals between blood donations.

CONCLUSIONS

The average drop in blood hemoglobin after the removal of 555 cc. of blood was 2.3 Gm.

The average time required to replace this amount of hemoglobin was forty-nine and six-tenths days.

The longer recovery periods were associated with a greater drop in hemoglobin and could not be correlated with the initial blood hemoglobin values. With a smaller donation and a smaller drop in the blood hemoglobin the recovery period was shorter.

Hemoglobin was regenerated in men at the rate of 0.049 Gm. per hundred cubic centimeters of blood per day under these conditions, and in women the increase was 0.040 Gm. per day.

Subsequent donations may be given with safety as soon as the blood hemoglobin has returned to its original level. An interval of three months should be allowed between blood donations if the hemoglobin of the donor is not determined regularly. The rate of hemoglobin regeneration after subsequent blood donations did not seem to be slower than after the first donation.

The administration of 1 Gm. of iron and ammonium citrates per day increased the daily hemoglobin regeneration by 49 per cent and shortened the recovery period from forty-nine and six-tenths to thirty-five and two-tenths days during the first period of its administration. It had progressively less effect after subsequent blood donations.

BLOOD PLASMA

ITS PLACE IN THE PRACTICE OF MEDICINE,
WITH SPECIAL CONSIDERATION TO THE
PROBLEMS OF PRESERVATION

MAX M. STRUMIA, M.D.

AND

JOHN J. MCGRAW, M.D.

BYRN MAWR, PA.

In previous papers we have discussed the technical details of various methods of preservation applicable to human blood plasma and pointed out certain limitations of each method.¹ In this paper we will discuss the effect that the various methods of preservation have on the quality and therapeutic value of plasma. Brief mention will also be made of the dosage in some of the more common conditions.

The following three premises seem generally acceptable: (1) blood plasma is used with satisfactory results in a large number of clinical conditions; (2) the effect of plasma depends on the action of certain elements contained therein; (3) these elements are variously affected by the manner of preservation of the plasma, as will be shown in this presentation. Acceptance of these three premises justifies the conclusion that any method of preservation applied to human plasma will profoundly influence its therapeutic value, and for this reason it is essential for the clinician to have a clear understanding of the changes caused by certain methods of preservation.

EFFECT OF PRESERVATION ON THE SAFETY OF PLASMA

In considering the value of any therapeutic agent, first consideration must be given to the possibility of harmful effects on the patient. Pooled or diluted human plasma separated with ordinary aseptic precautions from citrated blood immediately after collection and administered at once to the patient has proved free of reactions save for mild urticarial manifestations. This strictly fresh plasma is an ideal blood substitute, but its routine use is not practicable. To serve all its purposes blood plasma must be available in a form not requiring time-consuming preparation before administration.

In the development of methods of the preservation of plasma it must be remembered that the safety of the material may be affected by (1) the comparative ease of bacterial contamination and (2) the tendency of certain unstable proteins to form particles. Bacterial contamination has been responsible for most of the febrile reactions which have been reported² following the administration of plasma. Recently the report of a sudden death during the intravenous administration of unfiltered plasma³ has emphasized the absolute necessity of strict care in the prevention of flocculation or filtration to remove flocculi already formed. Microscopic examination of sections of lung tissue showed numerous small branches of the pulmonary artery blocked by emboli of fibrin-like material.

Both bacterial contamination and flocculation may be effectively prevented by rapid separation of plasma from freshly collected blood, followed by prompt fixation of plasma by freezing. Plasma may then be stored in the frozen state or, if it is considered desirable, dried from the frozen state.

Proper restoration of frozen or dried plasma results in a liquid free from flocculi. It must be noted, however, that while plasma properly restored from the frozen state is practically indistinguishable from the original material, plasma restored from the dried state is turbid. This turbidity, however, does not apparently cause any untoward effects.

Complete details of a method of preparation of plasma and of preservation by freezing or drying may be found elsewhere.⁴

To complete the measures to be taken to insure a safe material, provision must be made to reduce an occasionally high isoagglutinin content by pooling from eight to twelve lots of plasma.

EFFECT OF PRESERVATION ON CERTAIN SPECIFIC ELEMENTS OF PLASMA

We will now compare various methods of preservation in general use, with special reference to the efficiency of each method in maintaining the original content of the various elements of plasma.

In the table are listed the clinical conditions in which plasma is most widely used, grouped according to the plasma fraction on which most of the therapeutic effect is based.

In general, the response to plasma transfusion is dependent on (1) the total protein content, (2) the specific and nonspecific antibodies and (3) the anti-hemorrhagic properties due in part to prothrombin. The practical application of this grouping to clinical cases demonstrates much overlapping, as most patients will benefit from more than one of the fractions mentioned, although in varying degrees. For this reason preserved plasma should be as nearly like the fresh material as possible.

USE OF PLASMA FOR TOTAL PROTEIN CONTENT

The large group of conditions (including shock and various forms of hypoproteinemia) which are benefited mainly by the total protein content of plasma are adequately treated by plasma preserved in any form provided it is pyrogen free and contains no flocculi. The

amount of protein lost by flocculation occurring in liquid plasma preserved at 4 C. is practically negligible. Flocculation is almost completely eliminated by preservation of plasma at room temperature (about 25 C.). Although desiccation of plasma apparently alters the albumin-globulin ratio as determined by the usual laboratory methods, no indication of alteration of the proteins is found in the cataphoretic pattern obtained by the Tiselius apparatus.⁵ Plasma that has been properly preserved in the frozen state and rapidly thawed⁶ appears almost identical to fresh plasma. This means of preservation is the only one to maintain maxi-

Chart 1.—Effect of various methods of preservation of plasma on complement titer. The amount of complement is inversely proportional to the thickness of the lines of the graph, thus:

No line 0 100% complement
Widest line +++++ no complement

mal content of all the specific elements. This is important in the treatment of many diseases requiring complement and prothrombin in addition to the total protein content, such as for example a patient suffering from shock with wounds likely to become infected, or a patient with hypoproteinemia and hypoprothrombinemia resulting from such conditions as liver disease, colitis and intestinal obstruction.

When hypoproteinemia is the indication for the use of plasma transfusion, the quantity to be administered is a major factor that will be considered later.

SPECIFIC AND NONSPECIFIC ANTIBODIES

Whereas the specific antibodies are relatively stable,⁷ the content of complement is considerably influenced by the means of preservation. Chart 1 shows the effect of the method of preservation on the complement content, as determined by amboceptor-hemolysin titration. The preservation of complement is optimal when the plasma is maintained in the frozen state, very satisfactory for almost two months when it is maintained at 4 C., fair when preserved by drying and poor at room temperature (about 25 C.). It must be mentioned that when serum

is dried in small quantities, in the order of 1 to 10 cc., preservation of complement is very good. Thus guinea pig serum for the complement fixation test is adequately preserved by drying in small quantities without previous addition of preservative. Results expressed in chart 1 are based on titration of plasma prepared by a standard technic described elsewhere,⁴ in which the citrated plasma is dried in lots of approximately 300 cc. containing from 17.5 to 18 Gm. of plasma protein in a 400 cc. bottle. It is possible but less practicable to dry this quantity of plasma in such a manner as to maintain a higher content of complement. In all the dried plasma mentioned in this article the residual moisture was less than 1 per cent. It must be mentioned also that all the plasma used in this investigation contained merthiolate in the proportion of 1:10,000. The effect of this preservative on the survival of the various elements of plasma is being investigated.

ANTHEMORRHAGIC PROPERTIES

In this review we will limit our observations mainly to the antihemorrhagic properties due to the prothrombin content. The loss of prothrombin in citrated blood kept at 4 C. has been reported repeatedly.⁸ As will be seen in chart 2, the preservation of prothrombin in liquid plasma at 4 C. is better than that reported for whole blood. The optimal method for preservation of prothrombin is again maintenance in the frozen state. Plasma dried from the frozen state and restored with sterile pyrogen-free distilled water or plasma stored at room temperature (about 25 C.) for even short periods shows almost complete loss of prothrombin. It has been suggested⁹ that prothrombin may be lost in the process of drying owing to the removal of carbon dioxide with resultant increased alkalinity.

DOSAGE OF PLASMA

It may be stated that the amount of plasma usually administered is smaller than the quantity necessary for best results. In referring to the dosage of plasma, it is far better to speak of the grams of protein contained in each dose rather than the total amount of fluid employed. This is desirable because of the wide varia-

Chart 2.—Effect of various methods of preservation of plasma on prothrombin content.

tions in the amount of sodium citrate and other solutions added to the whole blood at the time of collection, with resultant variations in the dilution of the plasma. If the protein content should be accepted as the standard

of dosage, it would allow for better understanding and comparison of reports from various groups of workers; it would render unnecessary a statement of the amount of diluting solution employed, and finally it would permit the clinician to know exactly what to expect out of any given plasma preparation.

In cases of shock with or without hemorrhage the usual initial dose of plasma is 35 to 36 Gm. of plasma proteins, corresponding to 500 cc. of undiluted plasma. Additional doses may be required up to two or three times this quantity. The dose for any patient is, of course, the amount needed to raise and maintain an adequate volume of circulating blood as evidenced by satisfactory pulse, blood pressure and blood concentration readings.

Burns require large amounts of plasma protein, depending on their extent. The immediate indication

of plasma proteins, or 10,000 cc. of undiluted plasma, in a period of twelve days. The results were satisfactory.

The dosage of plasma, when it is used for its content of specific and nonspecific antibodies, is a matter based mostly on clinical appraisal, and consequently the proper amount to be used is difficult to estimate accurately. In prolonged severe infections the role of plasma in correcting hypoproteinemia must be considered in addition to any effect of specific and nonspecific antibodies.

For prophylaxis or modification of many infectious diseases, especially measles and scarlet fever, the use of pooled adult plasma has given gratifying results. The average dose varies from 0.7 to 3.5 Gm. of plasma proteins, or from 10 to 50 cc. of undiluted plasma.

Hypoprothrombinemia is usually corrected well beyond the danger limit by the transfusion of 35 Gm. of protein (500 cc. of undiluted plasma). For routine use in difficult deliveries we keep on hand bottles of 12 to 15 cc. of undiluted frozen plasma, containing 0.85 to 1 Gm. of plasma proteins made from a pool of several fresh bleedings. This allows an easy means of raising the prothrombin level of the newborn in the shortest possible time.

SUMMARY AND CONCLUSIONS

1. Regardless of the means of preservation employed, plasma must be safe from the standpoint of (a) bacterial contamination, (b) presence of flocculent protein precipitates and (c) unusually high isoagglutinin titer.

2. The manner of preservation greatly influences the survival of various specific elements of plasma. To summarize: (a) Preservation of plasma in the liquid state at room temperature (approximately 25 C.) causes very little flocculation but rapid loss of prothrombin and complement. It should be filtered before use, and the danger of rapid growth of a chance contamination must also be kept in mind. The value of such material is limited almost entirely to the total protein content. (b) Preservation of plasma in the liquid form at 4 C. maintains a fair quantity of prothrombin and complement, for a period of approximately fifty days, but causes maximal flocculation within a few hours. Filtration is essential and the danger of bacterial growth from a chance contamination is not eliminated. (c) Preservation of plasma in the dried state effectively prevents bacterial growth and flocculation, but the regenerated material has lost almost all the prothrombin and a portion of the complement when drying involves quantities of 250 and 300 cc. It need not be filtered and permits concentration if desired, but it is of little value for hypoprothrombinemia. (d) Preservation in the frozen state prevents bacterial growth and flocculation and at the same time insures almost complete preservation of all specific elements, including prothrombin and complement. After proper thawing it need not be filtered, and the therapeutic value is practically equal to that of freshly prepared plasma. Thawing must be rapid in the water bath at 37 C., and thereafter, until administered, the liquid plasma must be kept at room temperature.

3. The loss of essential elements occurring with preservation of plasma in the liquid state or in the dried form obviously limits the therapeutic application of plasma thus preserved. Plasma maintained in the frozen state and properly thawed is almost identical to the original material.

Clinical Indications for Plasma Therapy and Elements of Plasma Most Needed

Clinical Indications for Plasma Therapy	Elements of Plasma Most Needed
Shock (with or without hemorrhage)	Total Protein Content
Burns	
Hypoproteinemias	
Cerebral edema (concentrated plasma preferred).	
Hemorrhagic diseases (especially hypoprothrombinemia and hemophilia)	Prothrombin and other undetermined element or elements
Infections (including prevention of childhood exanthematic diseases)	Specific and nonspecific antibodies (complement)

for plasma in burns is usually that of shock, with correspondingly similar criteria for dosage. However, in extensive burns the prolonged and severe loss of plasma proteins and the resulting severe hypoproteinemia necessitate frequently repeated plasma transfusions. The hypoproteinemia is often particularly severe beginning from the third day. Plasma with a full content of complement would seem preferable in such cases in view of the frequency of infection of the denuded areas. The dosage of plasma in burns, beyond the original shock period, is best determined by the plasma protein content of the circulating blood, by the urinary output and by the occurrence of edema. A patient with severe burns extending over approximately two thirds of the body surface required approximately 700 Gm. of plasma protein (or 10 liters of plasma), the equivalent of forty lots of blood of about 500 cc. each. The patient made a good recovery.

The more chronic severe forms of hypoproteinemia may require relatively enormous amounts of plasma proteins to effect any significant change in the amount of circulating protein, although clinical results are often evident after much smaller doses. The lag in the rise of the patient's plasma protein is likely due to the tissue hypoproteinemia. The commonest forms of chronic hypoproteinemias are due to (1) excessive losses, as in nephrotic states; (2) diminished absorption, as in starvation and many gastrointestinal diseases; (3) faulty liver function, as in cirrhosis, and (4) a combination of any of these causes.

Thus a patient suffering from subacute hepatitis required 518 Gm. of plasma proteins, or 7,500 cc. of undiluted plasma, to tide him over a period of nineteen days including an extensive operation to relieve an obstruction at the ampulla.

A patient suffering from nephrotic hypoproteinemia in the course of a chronic nephritis required 710 Gm.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. FOWLER AND BARER AND
DRS. STRUMIA AND MCGRAW

DR. CHARLES A. DOAN, Columbus, Ohio: I have been interested in this problem of the reaction of the donor to the giving of blood for either plasma or whole blood transfusion purposes. It is important to recognize both psychic and physical factors which influence the immediate reaction in the individual donor. The amount of blood which may be removed without signs or symptoms of shock varies widely from donor to donor, and in the same donor at different times. Dehydration, extreme physical fatigue and mild upper respiratory infections definitely condition the donor's immediate response. In the normal, healthy, rested adult Dr. Moore and I have shown by blood volume studies immediately before and after donations an astonishingly prompt and rapid plasma replacement from the tissues with restoration of the original total blood volume within a few minutes or at most a few hours. Conversely, the average recipient shows an equally prompt displacement of plasma, commensurate with the new increment of cells received by blood transfusion, confirming the tendency to relative stability of total blood volume in each individual through the compensatory interchange of intravascular and extravascular body fluids. When these donors are studied in terms of the formed elements of the blood, as reported by Drs. Fowler and Barer, a much more variable recovery period is observed. Incidentally, one must not forget to discount technical and vasomotor factors in the interpretation of any single blood estimation. Drs. Fowler and Barer cite one donor who did not show complete cellular and hemoglobin reequilibration for ninety-eight days, as contrasted with only eighteen days required by another. There may be a critical level of iron reserves in the tissues of the body, which does not become evident until some such extra demand is made. Dr. Moore and I have shown that if the plasma iron is low, as for example in a mild hypochromic microcytic anemia, there will be very slow regeneration of hemoglobin following blood loss because of the lack of available iron reserves for the regenerative synthesis of hemoglobin. It is this same principle, which we apply in the treatment of polycythemia vera, when, after repeated venesection, erythropoiesis may be observed to have diminished appreciably coincident with the development of a low plasma iron and hypochromic microcytic red cells. Of course that is just what must be avoided in persons who generously donate blood for transfusion. Drs. Fowler and Barer have clearly demonstrated that iron, supplemental to the ordinary diet, will facilitate hemoglobin regeneration in the average healthy donor. If this is true for the male, it is doubly true for the mature menstruating female in my experience. The giving of iron routinely as a postdonation procedure would therefore seem to me to be desirable in most men and essential in all women donors.

DR. PAUL I. HOKSWORTH, Cincinnati: The most important contribution Drs. Strumia and McGraw have made is their report of results as to the prothrombin content of dried plasma, as opposed to frozen plasma. I have one question: Since the results in determination of prothrombin content are so variable when one uses different methods, might it not be possible in the future that they may alter their conclusion as to the prothrombin content of dried plasma or change some step in the process which will preserve prothrombin better? As a result of the careful study of the effects of the various technics and methods for the proper preservation of plasma by Drs. Strumia and McGraw and a number of other workers, there is no doubt that a valuable and safe blood substitute is being developed. A subject of equal importance is the making of this product available in the hospital of average size which holds no research subsidy. This institution is faced with the problem of supplying plasma by one of three methods: (1) by producing its own, (2) by purchase from a commercial house, (3) by participation in a plasma center supported by a group of hospitals. The first method, that of producing its own, presents the obstacle of cost. The expense of suitable personnel, equipment and adequate control of technics required to observe the best known standards of safety, which have been defined by Dr. Strumia and other workers, and of the collection, pooling, redistribution, processing

and preservation is certainly great. The second method, that of purchase from the commercial house, is even more prohibitive to the average patient, when amounts indicated in various clinical conditions often reach from 1,000 to 2,000 cc. or even more per patient. Not many physicians have patients who can afford from \$200 to \$400 or more for parenteral proteins. The third method, that of establishing a plasma center through the cooperative effort of a group of hospitals, offers much promise. Duplication of costs of equipment, personnel and operation is avoided. The ultimate expense of the product is reduced when friends and relatives of patients may serve as free blood donors. In addition, the medical direction of an organization of this kind can be readily secured on a volunteer basis among physicians who are interested both in having the advantages of a plasma center for their community and in contributing to improved knowledge concerning the entire subject. The university and general hospitals should lead the way in the development of such plasma centers.

DR. WILLIS M. FOWLER, Iowa City: With regard to the question which Dr. Doan raised as to the menstrual blood loss in female donors, we did not take that into consideration; but previous work has shown the average blood loss during the menstrual period to be about 50 cc. That will undoubtedly affect the recovery period to some extent and may account for the difference in the rate of recovery in the male and in the female. With regard to his second question as to varying dosages of iron, I do not feel that a larger dose of iron and ammonium citrate would cause a more rapid regeneration of hemoglobin under these circumstances than did the dose which we used. I believe that ferrous sulfate in a smaller dose would have the same effect as the iron and ammonium citrate. I feel that iron is not acting merely as a form of replacement therapy in these cases but that there is at least some degree of stimulating effect from the administration of the iron. We have given these blood donors iron after the first donation and then withheld it after a second and a third donation and then given it again after subsequent blood donations. The response to a second administration of iron is never quite as great as that obtained the first time it is given.

DR. MAX M. STRUMIA, Bryn Mawr, Pa.: I endorse Dr. Hoxworth's comments on the plasma center. It is only by the establishment of community collecting and distributing centers that an adequate supply of plasma will be made available not only for civil use but for use in emergencies, both local and general. We are trying to establish such a center, and many others are being established throughout the country. Concerning the question of prothrombin determination and prothrombin preservation in the dried state, I would say it is most essential, in order to obtain reliable data on the prothrombin time, that a technic be strictly standardized. We have used throughout our work a modification of the Quick method. The modification is especially directed to maintaining a set of rigidly enforced standards for both the prothrombin and the thromboplastic suspension. We have found that the best and by far the cheapest way to maintain both prothrombin standards and the thromboplastic suspension at a perfectly even keel is to keep both of these materials in the frozen state in any ordinary freezing cabinet. Thus for periods anywhere from fifteen days to four weeks and more, under certain conditions, one can be assured of having a perfectly unchanged prothrombin standard, as well as a perfectly unchanged thromboplastic solution, so that when one is doing serial determinations one is always using exactly the same unit to measure the thrombin time. Concerning the question Is there anything that may lead us to hope that in the future better preservation of prothrombin will be secured in plasma preserved in the dry state? We have about half completed studies that make us feel that a solution of the older problem is at hand. The loss of prothrombin in the dried plasma is quite likely connected with the greatly increased alkalinity of dried plasma. This increased alkalinity is due to two factors: first, the addition of sodium citrate to prevent coagulation; second, and perhaps a more important factor, the loss of serums during the drying period owing to the fact that we work under a high vacuum. If we regenerate plasma, as it is usually done, with plain, ordinary, sterile distilled water, the pH of the resulting solution is somewhere around 7.8 to 8.1.

If we buffer our sodium citrate, or if we regenerate our plasma in sterile water which has been saturated with carbon dioxide, we may obtain a remarkable preservation of prothrombin. When one regenerates plasma dried from the frozen state with distilled water which has been saturated with carbon dioxide one obtains a preservation in the neighborhood of 55 per cent. We are still below the optimal obtained by preservation in the frozen state, but since dried plasma has advantages under definite conditions we are hoping to be able to offer a solution of this problem by either one of these two methods mentioned.

CHRONIC ULCERATIVE COLITIS

A CLINICAL SUMMARY OF THE MANAGEMENT IN NINE HUNDRED AND TWELVE CASES

M. H. STREICHER, M.D.
CHICAGO

As in all scientific pursuits, in clinical medicine one invariably becomes tenaciously attached to the study of some entity yet unconquered. After many years physicians are still searching for a specific treatment for one of the most dreadful diseases in the abdomen, chronic ulcerative colitis. In this writing an attempt is made to outline and correlate the experiences I have had with 912 cases.

The essential diagnostic features that may influence the decision as to the type of management to institute are (1) the clinical history, (2) the pathologic conditions seen on proctoscopy and (3) the roentgenologic description of the extent of the disease and the degree of anatomic changes produced (table 1).

The important details related in any clinical history of an abdominal ailment have been well written up many times and need not be repeated.¹ Expert understanding and evaluation of the extent of the lesion of the mucosa of the colon is the most essential single factor in the determination of the type of management to pursue and of the prognosis. For instance, it is important to understand that a narrow lumen observed proctoscopically may mean severely edematous mucosa and not necessarily an absolutely irreparable anatomic constriction due to fibrosis. The treatment will of necessity be vitally different.

The fact that little new has been added to the establishment of specific therapy of chronic ulcerative colitis makes detailed discussions on the subject repetitious. There is, however, knowledge derived in recording large experiences grouped and summarized. The management in general resolves itself into a clearcut differentiation between acutely ill patients needing hospital care and chronically ill patients requiring occasional ambulatory treatment. For the acutely ill patient the main line of attack is chiefly supportive. It is essential to maintain good nutrition, to bolster the blood level by transfusions and to support the defensive mechanism by the administration of a high caloric and high vitamin diet.² All this must be done quickly to prevent a severe loss of body fluids, to stem a progressive decline in blood proteins and to combat severe toxemia.

The chronically ill patient is concerned mainly with maintaining well-being and avoiding recurrences. He

is resigned to the fact that he must learn to live with the disease and therefore wishes to be armed so that a useful life may be followed. An ambulatory patient must be on guard against sudden seasonal changes and against radical changes in the diet and must have sufficient rest. Nutrition must be maintained and foci of infection systematically attended to. In table 2 an outline of the management is given.

The introduction of therapy with sulfanilamide and its derivatives was received with relief, but, while almost miraculous results have been recorded in some isolated instances, use of these drugs in the treatment of chronic ulcerative colitis is hazardous.

Their specificity of action on infections due to *Streptococcus hemolyticus* has been established, but, while a small percentage of patients with chronic ulcerative colitis do harbor this streptococcus, the predominant bacterium present in the stool and obtained on culture is *Streptococcus viridans*. Any beneficial results obtained with any of these compounds in the treatment of chronic ulcerative colitis must therefore be considered incidental or secondary, due to an indirect action of the drug.

TABLE 1.—*Essential Diagnostic Features*

1. Clinical history
2. Proctoscopic data
 - A. Pathologic changes in colon
 - A. Inflammation and edema
 - B. Abscess formation (miliary)
 - C. Diffuse granular mucosa
 - D. Fibrous constriction of lumen
3. Roentgen data (barium sulfate enema)
 - A. Constriction of lumen of colon, longitudinal and transverse
 - B. Absence of haustra

TABLE 2.—*Management*

1. Acute stage (hospital care)
 - A. Bed rest
 - B. Blood transfusions (250 to 500 cc.)
 - C. Diet (basal plus high vitamin content including vitamin K)
 - D. Powdered opium, dilute hydrochloric acid, liver extract
 - E. Sitz bath, an oxycholesterol-petrolatum ointment, phenobarbital at bedtime
2. Chronic stage (patient ambulatory)
 - A. Diet high in vitamins
 - B. Powdered opium, dilute hydrochloric acid, liver extract, phenobarbital at bedtime, ferrous sulfate
 - C. Sulfanilamide derivatives
 - D. Vaccine (polyvalent)
 - E. Removal of foci of infection

My experiences concern the use and evaluation of sulfanilamide and two of its derivatives (table 3).

The results with sulfanilamide proved disappointing. The drug was given to 12 acutely ill patients and 5 chronically ill ones. All the acutely ill patients became considerably upset; vomiting ensued, diarrhea became exaggerated, blood appeared in the stool in larger amounts than usual and cramping in the abdomen became severe. Two ambulatory patients improved temporarily but with prolonged administration of the drug became very ill. At present I am dubious about employing sulfanilamide again in the treatment of chronic ulcerative colitis.

Azosulfamide merits a more favorable position. It is less toxic, it is tolerated better and it has the added advantage that, if desired, it may be administered parenterally during periods of suspension of oral administration. Azosulfamide was used in 18 cases of acute involvement with *Str. viridans* predominating and in 4 cases in which *Str. hemolyticus* also appeared in the

culture. Good results were obtained in 4 cases in which *Str. hemolyticus* was present in the culture. In the majority of the cases in this group there was no improvement with azosulfamide therapy. Such after-effects as eruptions on the skin, nausea, vomiting, jaundice and diarrhea were observed on many occasions.³

Total number of patients	68		11	7	50

* Summary: Sulfanilamide derivatives are most advantageous in cases of mild ulcerative colitis but too toxic in cases of acute involvement. Sulfathiazole gives the best results. Suggestion: The derivatives deserve a trial in the presence of *Str. hemolyticus*.

† C, chronic ulcerative colitis.

‡ A, acute ulcerative colitis.

As far as can be judged now, sulfathiazole seems to be the least toxic of the drugs for use in the treatment of chronic ulcerative colitis. It is not entirely free of toxic effects and there are individual idiosyncrasies, but nevertheless it is most advantageous. This drug, too, has demonstrated that sulfanilamide and its derivatives are most applicable in cases of mild ulcerative colitis and give the most promising results when *Str. hemolyticus* is present in the stool culture. Sodium sulfathiazole may be given intravenously to advantage if oral administration is suspended because of intolerance. The dose of the individual derivatives varies: with azosulfamide results have been obtained with a daily dose of 30 to 60 grains (1.9 to 3.8 Gm.), while with sodium sulfathiazole a dose of 1 Gm. every four to six hours for seven days may prove sufficient in alleviating an exacerbation of diarrhea. I have observed no advantage in the use of maximum doses.

Frequent observation of the patient's clinical course is essential to proper management. The most accurate index of the progress of the disease, however, is the amount of healing accomplished in the mucosa of the colon. This is determined generally by the clinical improvement in the symptoms but more accurately by repeated proctoscopic studies.⁴ My associates and I

have reexamined 283 patients (table 4) over a period of eight years and have classified them as unimproved, improved, cured or dead. The changes seen in the mucosa on reexamination were recorded and bacteriologic cultures were made so that a correlation of the proctoscopic findings might be established.

In the course of my studies I have learned that 20 per cent of the patients are eventually cured, 60 per

cent are definitely improved, 17 per cent are unimproved or have complications and 3 per cent die regardless of the type of treatment instituted.

The patients who cause most concern are the ones who become progressively worse regardless of the type of conservative management chosen.

True enough, conservative management at best is prolonged, tedious and difficult, gives no assurance at any stage that attacks will not recur and contains no absolute promise of a permanent cure. Of course, in cases of early, mild or moderately advanced involvement the results are more encouraging (20 per cent of the patients are cured and 60 per cent improved).

At present the most accepted opinion as to the surgical management of chronic ulcerative colitis is that if some drainage operation is undertaken an ileostomy is the procedure of choice.⁵

To get a cross section of opinion on this problem, I conducted a survey by mailing a questionnaire to one hundred gastroenterologists, proctologists and surgeons. In table 5 an abstract of the survey is presented.

The survey showed that of 286 ileostomies 11 were followed by a reanastomosis and that only 4 of the

TABLE 5.—Survey on Ileostomy

No.	Reanastomosis		Progress		Indications
	No.	Period	After Reanastomosis	After Ileostomy	
15	2	1-1½ yr.	1 fair	1 good	Polyposis, stricture
42	0	.		7 died	Irreparable damage, ileostomy a preparation to colectomy
35	0			1 died	Never in acute ulcerative colitis

4	1	2 yr.	1 poor	1 died	Polyposis, hemorrhage
5	0	.		1 satisfactory	
84	5	6 mo. 2 yr.	1 good	2 died 1 poor	Hopeless; male patients only
89	3	1 yr.	1	2 died	Acute colitis; few days of no response, obstruction
4	0	.		1 died	Obstruction
286	11		4	14 died	Stricture

patients made good or fair progress after the reanastomosis. Fourteen of the patients died before a reanastomosis was performed. The consensus was that ileostomy is indicated in the presence of polyposis, anatomic stricture of the colon beyond repair, abscess, malignant neoplasm, absolute obstruction, perforation or hemorrhage.

There were two sharply defined opposite opinions as to whether ileostomy should be performed during an acute exacerbation of chronic ulcerative colitis.

Among the reasons given why reanastomosis is not advisable was that the original disease invariably recurs. Another suggestion made was that ileostomy is not successful because it is not performed early enough in the course of the disease. Our experience shows (1) that the indications for ileostomy as given in the survey are satisfactory, (2) that patients with the disease in the acute stage should not be operated on, (3) that the disease recurs in the great majority of patients if reanastomosis is accomplished and (4) that it would be unwise to perform ileostomy during the

early stages of the disease because in the early stages one can accomplish a cure or definite improvement without ileostomy.

Therefore, as the results after ileostomy are so poor, one would strongly suggest that conservative management be maintained as the treatment of choice and that ileostomy be reserved for the patient in whom the colon has undergone irreparable damage.

185 North Wabash Avenue.

ABSTRACT OF DISCUSSION

DR. MARTIN S. KLECKNER, Allentown, Pa.: The clinical history, the findings on proctosigmoidoscopic study and roentgenologic studies tell us how extensive the pathologic change in the colon has become. This is repeatedly necessary if we wish to note the progression or ameliorization of chronic ulcerative colitis. The problem of therapy is still unsatisfactory. Not knowing whether this disease is due to avitaminosis, a streptococcal infection or otherwise, we give these patients varied types of treatment, primarily medical, and often advise some surgical procedure as ileostomy in an effort to sidetrack the infection or remove it by colectomy. Our results have been gratifying at times, but in these cases, in 20 per cent of which operation is performed, we are disappointed by the end results. Every patient with chronic ulcerative colitis must be forcibly impressed with the importance of following the strict routine. It has been my practice at the onset to make repeated stool examinations in all cases in which any ulcerative process, other than a malignant growth, exists. Even in the absence of definite bacilli, cocci or amebas in chronic ulcerative colitis I routinely give these patients a course of emetine hydrochloride (hypodermically) $\frac{1}{2}$ grain (0.03 Gm.) twice a day for four days, followed by carbarsone (by mouth) in 4 grain (0.25 Gm.) capsules twice a day for ten days. After the last capsule and an interval of two weeks, the patient again receives the same treatment. Iron by mouth, vitamins B, C and D and calcium gluconate are always prescribed. The patient is placed on a low residue high caloric diet, given plenty of fluids, and told to inject 1 to 2 ounces of 1 to 5 per cent zinc peroxide or 6 per cent bismuth subgallate in olive oil into the rectum once or twice daily (after preliminary cleansing with warm saline solution). The patient is urged to retain the injection for at least an hour. When possible rest in bed, especially in the acute cases, is an important requisite. My apparent successes and failures correspond in almost like percentage with those of Dr. Streicher. The sulfonamides have been tried during the past year in a series of 12 cases with the following results: Two cases (six and eight months) showed a phenomenal clearing up of all symptoms by the use of sulfathiazole. One case (one and one half years) became entirely clear of ulceration. Eight cases showed no response to sulfonamide derivatives and it was necessary to stop its administration in 2 because of nausea. Sulfonamides should be tried in special cases, but the results obtained must not be too enthusiastically received.

DR. ZACHARIAS BERCOVITZ, New York: Dr. Streicher's results in chemotherapy are essentially in agreement with my own. He has called attention to the astounding results of treatment in some isolated instances. When dealing with a progressive disease such as chronic ulcerative colitis, we have no specific cure and, therefore, therapeutic results must be interpreted cautiously. The criteria for evaluation of any method of therapy in ulcerative colitis must include the following: 1. Before any new method of therapy is applied, the patient must be placed on the basic regimen and must be under observation over an adequate period of time. 2. Five years' observation under the new method of therapy is necessary. This allows for patients who improve spontaneously or who seem to improve with change of season or treatments. Also it allows sufficient time to secure an adequate series of cases. The five year rule gives the doctor time to discover whether or not his enthusiasm for any special therapy was justified. 3. Enough control cases must be treated on the basic regimen over the same length of time in order to allow for individual variations in the disease. The basic regimen which I observe in chronic ulcerative colitis

is essentially the same as Dr. Streicher's. Briefly it involves blood transfusions, dextrose infusions given in physiologic solution of sodium chloride and absolute rest in bed. 4. A diet high in proteins, vitamins and calories is prescribed, to be served in attractive form and given in adequate quantities. 5. Hydrochloric acid and pepsin for protein digestion are essential. 6. Adequate vitamins must be given. Liver extract does not cure chronic ulcerative colitis, but it should be included as a valuable adjunct in every regimen. The surgical problem in chronic ulcerative colitis is fundamentally to determine just when a patient should be operated on. We have not had the courage to face the stark reality that with the exception of a few cases which seem to improve spontaneously the disease is progressive in spite of the best management. We procrastinate until the patient's morale and vitality are gone and complications such as stricture or perforation force surgical intervention. Under these conditions the results of surgery cannot be what they should be, and restoration of bowel function is jeopardized. As soon as the true nature of the disease is established, ileostomy should be performed and then we may be able to offer some of the patients some hope of recovery.

DR. ISAAC R. JANKELSON, Boston: I have treated colitis in the same way as the author; however, I cannot record a 20 per cent cure either in the early or in the advanced stages of ulcerative colitis; in fact, I do not speak in terms of cure; I speak in terms of remissions for several reasons. The first reason is that no definite criteria exist by which one can establish a long distance prognosis in any case. Second, I have seen only too often patients who returned to the hospital with a recurrence often worse than the original attack. I have tried various so-called specific remedies proposed at various times, including the sulfonamide derivatives. My experience was that a few cases responded excellently, some fairly well, but the vast majority remained about the same; in fact, I know of only one cure of ulcerative colitis, and that is the surgical extirpation of the colon. In my own experience the operative mortality of an ileostomy is about 18 per cent and that is approximately the mortality reported from other clinics. Since the operation is technically simple, I believe that this mortality must be ascribed to the medical man and not to the surgeon, because the patient is sent to the surgeon altogether too late, at a time when even a simple surgical procedure will probably terminate fatally.

DR. J. ARNOLD BARGEN, Rochester, Minn.: I should like to put my remarks in the form of two questions: 1. Would it not be best to classify chronic ulcerative colitis according to etiologic types? 2. Would it not be best to attempt to treat these etiologic types specifically? I should like to amplify these questions. In recent years we have recognized a streptococcal ulcerative colitis, an amebic ulcerative colitis, a tuberculous ulcerative colitis, an ulcerative colitis due to vitamin deficiency, an ulcerative colitis due to the virus of lymphopathia venereum and a large number of patients with ulcerative colitis of unknown etiology. In my experience the streptococcal type constitutes by far the largest number of cases. The group in which the cause is still unknown has become smaller. Allergy plays a part in some cases of ulcerative colitis but I am not yet convinced that it is an etiologic factor in itself. Nevertheless, just as in infections in any other organ, the cause should be ferreted out first and the treatment instituted accordingly. I get the impression from the discussions that the tendency is to treat all forms of ulcerative colitis as if they were a single entity. Results of treatment will be infinitely better if this consideration is adhered to. A word about surgery: Patients with the streptococcal type of ulcerative colitis will rarely require surgery, but if and when the time comes for this because of one or many of the serious complications that occasionally afflict these patients or because of a very advanced disease, an ileostomy will be the only surgical maneuver to be considered. However, in the patients with ulcerative colitis of indeterminate etiology involvement of the bowel is often segmental and here ileocolostomy and subsequent partial resection of the colon may result in relief.

DR. DAVID J. SANDWEISS, Detroit: I have recently encountered a case of severe ulcerative colitis of long duration, treated without success by the usual methods, but elimination of milk from all elements of the diet resulted in improvement.

Milk always initiated an attack. I considered this a case of milk allergy. I wonder how many of Dr. Streicher's patients were found to be allergic to certain foods which, when removed, resulted in improvement of the condition.

DR. RACHELLE SELETZ, Los Angeles: I should like to voice my protest against the tendency to omit local therapy in colitis. I feel that a great adjunct to the therapy of certain types of colitis is lost here. It may sound reactionary, because in the past there have been a lot of deleterious effects from local therapy. That was because destructive medications, such as silver nitrate, were used. But in view of the fact that a lot of purulent material can collect behind the valves and because of the spasticity, the ulcerated surfaces are constantly touching one another and are further traumatized. I feel that if we can apply such soothing medications as mercurochrome (aqueous solution) and liquid petrolatum, we shall use them not as bactericidal agents but as bacteriostatic factors to seal over and protect the mucosa. At the same time these medications are inimical to bacteria and other organisms that may invade the traumatized mucosa. In this way we shall gain a lot by protecting the bowel from further injury.

OPERATIVE TREATMENT OF CEREBRAL PALSY OF SPASTIC TYPE

WILLIAM T. GREEN, M.D.

AND

LEO J. McDERMOTT, M.D.

BOSTON

In surgical procedures directed toward chronic disease impressions of results are often misleading. It is necessary to pause at intervals and do end result determinations on groups of cases to make decisions as to the efficacy of various procedures. It has seemed wise to us to review the orthopedic operations for cerebral palsy of the spastic type which have been done during the preceding fifteen years, 1925-1940, at the Children's Hospital in Boston. In addition to these cases, we have added certain ones in which operations were done by one of us at the Peter Brent Brigham Hospital.

The cases included are those which might be called by the orthopedist spastic paralysis and by the neurologist cerebral palsy of the pyramidal tract type. For practical purposes, we have emphasized the term spastic paralysis, since spasticity from whatever origin—intracranial or spinal—was the criterion by which patients were placed in this series.

In all there were 421 operations on 160 patients, the majority of whom were under 12 years of age. Only 20 were over this age at the time of the procedure. In 88 per cent of the operations sufficient data were available for an evaluation of the end result. In 219 of the 421 operations we were able to evaluate the result by a physical examination during the current year. The average follow-up interval was six years and eleven months.

Among the 160 cases there were 9 instances of monoplegia, 73 of hemiplegia, 51 of paraplegia, 2 of triplegia and 25 of quadriplegia.

Seventy-nine of the patients were considered mentally normal and 27 questionably so. Thirty-seven were definitely retarded and 30 were feeble-minded.

This study was aided by a grant from the Children's Bureau of the United States Department of Labor.

Read before the Section on Orthopedic Surgery at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

From the Orthopedic Service of the Children's Hospital, the Peter Bent Brigham Hospital and the Department of Orthopedic Surgery, Harvard Medical School.

Before the data are considered from this survey, it is well to consider our attitudes regarding the position of surgical procedures in the treatment of spastic paralysis, since in general the patients were chosen for operation with these considerations in mind.

POSITION OF SURGERY IN TREATMENT

Operations, important as they are, should be considered as an adjunct to the general plan of therapy. By the nature of the process which interferes with the normal motor pathways, the patient is forced to depend on accessory tracts and to adjust his motor mechanism to an awkward type of innervation. Training of this mechanism is the primary treatment, whether directed or undirected. Surgical procedures, by reducing deformity, establishing better balance of muscle power, decreasing the spasticity of muscles and simplifying the problem of control, are often an indispensable part of the process of rehabilitation. In many cases, however, surgical procedures are not indicated either by the nature of the process or by the other delimiting factors.

Certain basic criteria must be established before decisions are made regarding an operation, all dependent on a thorough evaluation of the patient. The type of paralysis and the degree of motor inadequacy must be classified as accurately as possible. Occasionally this may be difficult, as in the differentiation between true athetosis and certain instances of spastic paralysis with definite accessory motor overactivity. Ordinarily observation for a short period enables the differentiation to be made.

It should be determined whether the patient has sufficient sense of balance to allow the intended result. If a patient cannot maintain a sitting position it cannot be expected that operations on the lower extremities will allow him to walk. There is ordinarily no need for correction of deformities in the lower extremity unless walking can be attained; the deformities will only recur.

The mental status of the patient is an important consideration in deciding whether an operation should be done and what procedure should be performed. Operations on the upper extremities are rarely indicated on patients who have gross mental deficiency, nor are finer adjustments in the motor mechanism of the lower extremities to be attempted on such a patient. However, operations should be performed on patients who cannot walk if it is felt that they may be made to walk either alone or assisted, even in the presence of well defined feeble-mindedness. The ability to walk facilitates their care, even if they are totally dependent in other ways.

For patients of low mental status definitive procedures in which the factor of muscle training is less important should be chosen. Prolonged expensive training and hospitalization are not indicated.

A detailed examination of the muscles should be made. Not only must the spastic muscles be recognized and charted but, as emphasized by Phelps,¹ the power of the other muscles must be evaluated and their degree of control noted.

The importance of evaluating the power of nonspastic muscles is emphasized by the fact that, as pointed out by Phelps,¹ certain antagonistic muscles may show great weakness and, for practical purposes, even complete flaccid paralysis. This is particularly true in the

1. Phelps, W. M.: The Care and Treatment of Cerebral Palsy. J. A. M. A. 111:1 (July 2) 1937.

muscles controlling the distal ends of the extremities. A flail paralysis may arise from a cerebral lesion, as pointed out by Fulton.² On the other hand, long continued deformity may of itself cause the stretched muscles to lose power, which power will return when the deformity is corrected. If there is actually a flaccid paralysis in the antagonistic muscles, merely relieving the spasticity will not solve the problem.

The age of the patient is a delimiting factor. A certain type of operation may be done as a temporary measure at a younger age to facilitate function, although it is anticipated that it will be followed by another when the patient is older.

In considering the operative approach in an individual case, one should remember that the correction of one deformity reduces the problem of the patient in his total motor control.

METHOD OF END RESULT EVALUATION

In this study primary attention was given to the classification of the result from individual operations, with secondary attention to the general effect. Three types of evaluations were made in all our cases.

TABLE 2.—Lengthening of Heel Cord (Total Operations One Hundred and Twenty-Five)

Result	Number of Operations	Per Cent				
Excellent.....	12	11.2				
Good.....	34	31.5				
Fair.....	37	34.6				
Poor.....	24	22.4				
No examination.....	18				
Rating of Improvement in whole group:						
Total	++++	+++	++	+	0	No Examination
125	18	40	25	11	13	18
Of those rated poor:						
75% were in children in motor status 1 or 2						
50% were in feeble minded children						
6 secondary lengthenings were done:						
2 good; 2 fair; 2 poor						
14 patients had arthrodeses later						

Operations were classified under "excellent," "good," "fair," "poor" and "no examination." For this purpose an objective standard was established as a result from each type of operation, based on the postoperative function. Space does not allow for the description of the criteria used in establishing these standards in each individual procedure.

The second classification was a rating of improvement, which was founded on a comparison of the final status with the initial one. This was recorded as + + + +, + + +, + +, +, 0 and no examination; 0 improvement indicated that the individual was unimproved and + + + + indicated striking improvement.

As a further method of evaluation, patients were classified as to "motor status." This classification was based on the motor potentialities of the patient and took into consideration the amount of spasticity, incoordination, overflow responses and balance. Motor status 1 was the lowest classification and 5 was the highest. In this particular paper we shall refer to motor status 1 and 2 only.

OPERATIONS ON THE LOWER EXTREMITY

Of the 421 operations in this series, 379 were done on the lower extremity and 228 of these were done for deformities of the foot.

Equinus due to spasticity and contracture of the gastrocnemius and soleus were the deformities most usually found, but deviations of the foot in a lateral direction (varus or valgus), deformities of the toes and weakness of the muscles of dorsiflexion complicated the problem in many instances.

TABLE 3.—Neurectomy—Gastrocnemius—Stöffel (Total Operations Nineteen)

Operation On	Result				
	Excellent	Good	Fair	Poor	
" "	2	1	2	2	
" "	0	0	2	2	
Nerve with lengthening gastrocnemius, upper	0	4	2	2	
Total.....	2	5	6	6	
Rating of improvement in whole group:					
Total	++++	+++	++	+	0
19	6	3	7	1	2

The criteria for an excellent operative result on the foot were active and passive dorsiflexion to approximately a right angle, no significant abnormality of weight bearing in a lateral direction and the ability to go up on tip toe. The maintenance of a take off is important. In many instances the general status of the patient precludes such a result.

Lengthening of Heel Cord.—Lengthening of the heel cord was done in 125 instances, in all by plastic lengthening (table 2). As may be noted, 12 of the operations were recorded as "excellent" and 34 as "good," in comparison with 37 which were graded "fair" and 24 "poor." A comparison of the "rating of improvement" shows that the patient in 13 instances was unimproved after the operation. Of those operations rated "poor," 75 per cent were on patients in "motor status 1 or 2," which is the lowest classification, and 50 per cent were on feeble minded children.

In 20 instances further operations were done to relieve the deformities of the feet. Six secondary operations for lengthening of the heel cord were carried out. Two of these were "good" subsequently, 2 "fair" and 2

TABLE 4.—Foot—Arthrodesis, Tendon Transplant (Total Operations Fifty-One)

Operation	Result					No Examination
	Total	Excellent	Good	Fair	Poor	
Triple arthrodesis alone	23	5	6	10	2	0
Countersinking (Brewster)	7	3	3	0	1	0
Subastragalar arthrodesis	2	0	1	0	1	0
Wedge tarsectomy.....	2	2	0	0	0	0
Arthrodesis with tendon transplant	14	4	5	0	1	4
Tendon transplant without arthrodesis	3	1	1	1	0	0
	51	15	16	11	5	4
Most common transplants						
Posterior tibial forward; extensor hallucis to first metatarsal; anterior tibial over						
Rating of improvement in whole group:						
Total	++++	+++	++	+	0	No Examination
51	14	11	15	2	5	4

"poor." After 14 of these operations it was found necessary to do an arthrodesis of the foot.

In those in the "poor" group, the most common finding was a recurrence of the equinus. In many instances this arose incident to weakness of the muscles

2. Fulton, J. F.: Paralysis of Cortical Origin: A Physiological Analysis of Flaccid and Spastic States in Monkeys and Chimpanzees. Proc. California Acad. Med. 4: 1, 1933-1934.

of dorsiflexion. Often postoperative care was not carried through in satisfactory fashion and the result was greatly compromised.

Neurectomy—Gastrocnemius.—Neurectomy of the nerves to the gastrocnemius muscle by the Stöffel³ technic was done in 19 instances only (table 3). In 2

than "fair," and the 2 cases which were rated as "poor" showed a calcaneus deformity of significant degree.

Of other procedures affecting equinus, lengthening of the upper end of the gastrocnemius was done in 15 instances. In 4 of these neurectomy to one head of the gastrocnemius was an accompanying procedure. The result from this operation will be discussed later.

Arthrodesis-Tendon Transplantation.—The cases which presented arthrodesis of the foot and those in which tendons were transplanted in this area were grouped together, since tendon transplantation usually was accompanied by arthrodesis. The results of the various procedures were considered separately (table 4). There were only 3 cases in which tendon transplantation was done without an arthrodesis.

Forty-eight arthrodeses were done. The predominant procedure was a triple arthrodesis of the Hoke⁴ type

Fig. 1—A, a boy aged 4 years and 2 months showing equinus deformity prior to lengthening of the heel cord. B, same patient four years later; recurrence associated with flaccid paralysis of the muscle of dorsiflexion and poor postoperative care.

the nerve to the two heads of the gastrocnemius was divided; in all others the nerve to one head only was interrupted. In those in which the division of the nerve was done without other procedures the results were

Fig. 2.—Same patient as in figure 1, showing position of feet at 9 years, fifteen months after triple arthrodesis on the right.

equally distributed among "excellent," "good," "fair" and "poor." The "excellent" results occurred in 2 cases in which the spasticity and deformity were mild. In those in which lengthening of the achilles tendon accompanied the division of the nerve, no results were better

Fig. 4.—Boy aged 11 years unable to stand one year before. Status after bilateral adductor myotomy and obturator neurectomy, triple arthrodesis, lengthening of hamstrings and heads of the gastrocnemius. Walks alone. Significant decrease in accessory motions after operation.

or one of its variations. Seven countersinkings, as described by Brewster,⁵ were in the series. In 14 cases the arthrodesis was accompanied by tendon transplantation.

Analysis reveals that this group, that is, arthrodesis with or without transplantation, showed by far the best results of the operations that were performed on the foot. Of the total of 51 operations, 31 were recorded as "good" or "excellent." Countersinking and arthrodesis with tendon transplantation were the two procedures which gave the best results. The tendon transplantation most commonly done was the posterior tibial into one of the metatarsals. In 1 instance it was necessary to transplant tendons into the os calcis to relieve calcaneus which had followed a tenotomy, not a lengthening, of the achilles tendon.

⁵ Brewster, A. H.: Countersinking of the Astragalus in Paralytic Feet. *New England J. Med.* 209:71 (July 13) 1933.

Operations on the Foot.—A comparison between the various summary groups of operations on the foot is not possible without a consideration of the various indications and the position of the procedures themselves in the total picture. Lengthening of the heel cord and neurectomy of the supply to the gastrocnemius can correct only the equinus—the former by lengthening the muscle and decreasing its arc of contraction, the latter by actually decreasing the muscle mass which has the ability to contract. Neither can directly stabilize the foot in a lateral direction, nor can the element of foot drop be corrected if the anterior muscles do not develop power after the deformity is relieved. Despite this, they have a definite place in the total program.

In our cases, neurectomy of the gastrocnemius has not been employed often and has been used in instances in which the deformity was not severe. It is our feeling that unless the deformity is mild and can be corrected easily under anesthesia, other procedures are preferable to neurectomy.

Lengthening of the heel cord is an excellent procedure in many instances, provided certain rules are observed. The heel cord should not be lengthened too much and

Fig. 7.—Hips held in abduction with bivalved plastic splint after adductor myotomy and obturator neurectomy.

must be as firmly sutured as any tendon transplant. The part should be immobilized at a right angle with the knee straight until firm healing has occurred. Following this, the foot should be maintained in the correct position, both by the use of night casts for a prolonged period and by exercises in dorsiflexion. Failure to do this was a common factor in the majority of our "poor" results. If the correction becomes stabilized, and if there is power in dorsiflexion, a "good" result may be expected. At any rate, it is a procedure which we do at an age when arthrodesis is contraindicated. It allows the progress of training and often solves the problem entirely. The fact that an arthrodesis may be necessary later does not indicate that lengthening of the heel cord has not had its place.

Arthrodesis is helpful in the older patient, either as a primary procedure or a secondary one, although it should rarely be done on children aged under 8 or 9 years. By attention to the pattern of arthrodesis the equinus as well as lateral deformity may be corrected. Foot drop and recurrent equinus may be obviated by a posterior block, which in our series has been accomplished by a countersinking or by correcting the foot with the astragalus in full plantar flexion. If controllable muscles are available, their transplantation has solved the problem of foot drop and recurrence of

deformity in even better fashion. Arthrodesis of the midtarsal joints simplifies the control of the foot in a manner which cannot be accomplished in any other way.

DEFORMITIES OF THE KNEE

Operations about the knee in this series were designed to relieve flexion contraction. Hyperextension may be a feature of the gait in spastic paralysis, but unless it is a complication of an operative procedure it depends ordinarily on an equinus deformity of the foot with tight heel cords. Milder degrees of flexion contracture were not operated on in this series.

Fig. 8.—F. D., a girl aged 9 years and 9 months, with left hemiplegia, showing limitation of supination on the left side with inability to dorsiflex the hand.

The most frequent operation was lengthening of the hamstring tendons, which was carried out by one technic or another in 59 instances. In 11 the procedure was accompanied by division of the iliotibial band and intermuscular septum after the technic of Fitchet.⁶ In the earlier cases of the series, tenotomy of the hamstrings rather than plastic lengthening was the rule. Thirty-five operations were done in this fashion (table 5): Lengthening of the hamstrings in a plastic manner was done in 24 instances.

Of the whole group, independent of method, the results in 11 cases were "excellent," 21 "good," 9 "fair" and 16 "poor" and in only 2 was an end result evaluation not possible.

Again the general motor status and the mentality of the patient were prominent factors in the end result. Of those rated "poor," 87 per cent were in patients with "motor status 1 or 2" and 63 per cent were in feeble-minded patients.

In this series the procedure giving the best results in flexion deformity of the knee has been a combination of lengthening of the hamstrings with a lengthening of the tendinous origin of both heads of the gastrocnemius.⁷

Fig. 9.—Same patient as in figure 8. *A*, range of active supination ten months after transplantation of the flexor carpi ulnaris to the extensor carpi radialis longus. *B*, phantom photography showing amount of active dorsiflexion possible at this time.

DEFORMITIES OF THE HIP

Of deformities involving the hip joint, adduction, with a resultant scissors gait, is in the majority of instances the most disabling. This adductor deformity may be accompanied by abductor weakness. Flexion

6. Fitchet, S. M.: Flexion Deformity of the Hip and the Lateral Intermuscular Septum, *New England J. Med.*, 209: 74 (July 13) 1933.
7. Green, W. T., to be published.

deformity of more or less degree is often seen, although its presence in severe degree is not common, unless the patient is older and has spent a considerable period without walking. Internal rotation is a frequent deformity, but ordinarily it is not severely disabling

TABLE 5.—Lengthening of Hamstring Tendons
(Total Operations Fifty-Nine)

Operation	Total	Result					No Examination
		Excellent	Good	Fair	Poor		
Lengthening of all hamstrings	9	0	7	0	2		0
Lengthening of all hamstrings plus both heads of gastrocnemius	15	7	6	0	2		0

Tenotomy of medial hamstrings	5	0	0	3	2		0
Total.....	59	11	21	9	16		2

In 11, iliotibial band and intermuscular septum (Fitchet) were divided

Rating of improvement in whole group:

Total	++++	+++	++	+	0	No Examination
59	20	13	8	4	10	4

Of those rated poor:
87% were in children in motor status 1 or 2
63% were in feeble-minded children

Of those unimproved:
All were in children in motor status 1 or 2
60% were in feeble-minded children

and may often be taken care of by training if the other deformities are corrected.

There were 77 operations performed for deformities of the hip. Adductor myotomy with obturator neurectomy by varying technics, which was done in 66 instances, was the most frequent operation (table 6). The procedure that was most used was neurectomy of the anterior branch of the obturator nerve accompanied by myotomy of the adductor longus and brevis and of a few fibers of the magnus. In only 2 instances was it described that both anterior and posterior branches of the obturator nerve were divided. Results from the operations for adduction deformity were disappointing and were contrary to our impression. Twenty-three of the 66 operations were recorded as a "poor" result, 20 as "fair," 11 as "good" and only 4 as "excellent." No examination was done on 8. Twelve were unimproved.

Sixty-one per cent of those in the "poor" group were in "motor status 1," but only 22 per cent were feeble-minded children. The reason for the "poor" result in all instances was recurrence of the deformity.

In an evaluation of the causes of the recurrence, three factors were determined to be in large part responsible:

1. The patient was not held long enough in the abducted position after operation.
2. Physical therapeutic measures were neglected.
3. The procedure was not extensive enough.

It is our feeling that in the adductor operations, as in all others, the parts must be retained for a considerable period in the corrected position at least part time. In practice this is accomplished mainly by the use of night casts; and it is our custom at this time to retain the parts in abduction, using two bivalved cylinders which are held apart by struts, in the fashion illustrated in figure 7. This is more comfortable than a spica.

It may be necessary to use this for many months in order to stabilize the position. Frequently there

is weakness of the abductors. Maintaining the corrected position and giving exercises in abduction allow this to be counteracted.

Of procedures carried out at the hip to relieve flexion contracture, fasciotomy after the manner of Ober⁸ was done in 3 cases; the Soutter⁹ operation was done once. All gave improvement. In 2 instances the origin of the tensor fascia femoris was transplanted backward on the ilium after the manner of Legg¹⁰ for internal rotation deformity and to give increased power of abduction. Both purposes were served in these 2 operations. Partial division of the gluteus medius and minimus after the manner of Durham¹¹ was done once in this series and resulted in improvement. Any procedure that weakens abductor power should be avoided.

As a total expression of the operative result in the lower extremities, an analysis was made of the group of patients who were unable to walk on admission. Thirty-one of the 160 patients were unable to walk prior to operation. Six of these were still unable to walk after the operation; 11 walked with assistance, that is with braces and crutches in combination or separately, and 9 were able to walk alone. On 5 there was no record. Of the 12 patients who walked with support before operation, 5 were able to walk alone, 4 still needed assistance and 1 was unable to walk. The latter had a progressive degenerative disease.

The average age at the time of operation of those not walking was 6½ years. Only 2 patients in this group were operated on before 3 years of age and 16 were operated on after 5 years of age.

All patients who were unable to walk postoperatively were quadriplegic.

THE UPPER EXTREMITY

The number of operations in the upper extremity was relatively small, 42 out of the total of 421. Pronation and flexion deformity of the wrist were the most frequent indications for operations.

TABLE 8.—Operation on Forearm (Total Operations Twenty-Eight)

Operation	Total	Result					No Examination
		Excellent	Good	Fair	Poor		
Neurectomy—pronator teres (Stöffel)	19	4	1	4	4		6
Tendon transplant, flexor carpi ulnaris to extensor carpi radialis longus	9	6	2	1	0		0

Stöffel—pronator....	19	2	3	3	3	6
Ulnaris transplant...	9	6	2	1	0	0

Three patients with a Stöffel operation after which little improvement was shown were definitely improved following ulnaris transplant

For pronation deformity, neurectomy of the branch of median nerve to the pronator teres was done in 19 instances. Of these, 4 were rated as "excellent," 1 as "good," 4 as "fair" and 4 as "poor," with final evaluation not being made in 8 (table 8). This procedure relieves

the spasticity of the pronator teres and allows the patient to develop better supination. With removal of this difficulty in control, general function of the wrist and hand may improve.

Pronation and flexion deformity of the wrist are often associated with weakness of the extensors of the wrist as well as with spasticity and contracture of the flexor carpi ulnaris. In such instances tendon transplantation of the flexor carpi ulnaris to the extensor carpi radialis longus tendon may be done in such a manner as to promote both extension of the wrist and supination.⁷

We have been pleased with the results of this procedure and it has been much more satisfactory than neurectomy to the pronator teres. In 6 of the 9 operations done, the result is classified as "excellent," in 2 "good" and in 1 "fair." All patients showed improvement.

Transplantation of the flexor ulnaris tendon removes it as a deforming factor, both in flexion and in ulnar deviation, and allows it to assist in active dorsiflexion and supination.

Operations in the upper arm in our series were rare indeed. Four operations were done. One of these was a tenotomy of the insertion of the latissimus dorsi and teres major; 3 were neurectomies to major muscles. In all instances the neurectomies were only partial, that is the total innervation of the individual muscles was not divided. All those procedures resulted in improvement, as may be seen in table 9.

SUMMARY

1. A study has been made of the results of 421 orthopedic operations on 160 patients with spastic paralysis which have been done during the past fifteen years. In 88 per cent an end result classification has been made. "Spasticity," independent of its origin, has been the criterion by which cases were included in the group.

2. The patients operated on in this series were delimited by the attitude that:

(a) Surgical procedures are an adjunct in the general plan of therapy for spastic paralysis.

(b) Orthopedic operations on patients with cerebral palsy of the extrapyramidal type are not often helpful.

(c) Operations are indicated in only a certain proportion of spastic paralysis, depending on the nature of the deformity and the general status of the patient.

3. Two hundred and twenty-eight of the operations were done for deformities of the feet. Lengthening of the heel cords, arthrodesis and neurectomy affecting the gastrocnemius were done in that order of frequency. Arthrodesis gave the best results, although comparisons are not valid. Lengthening of the heel cord is a good procedure provided certain principles are followed. Tendon transplantation is helpful in deformities of the foot.

4. Lengthening of the hamstring tendons was the most common operation at the knee. The results were better in those instances in which it was accompanied by lengthening of the upper end of the gastrocnemius.

5. The results from obturator neurectomy with adductor myotomy were disappointing, although all but 12 of the 66 resulted in improvement.

6. Division of the branch of the median nerve to the pronator teres was helpful in correcting pronation deformity.

7. Transplant of the flexor carpi ulnaris to the extensor carpi radialis longus was an excellent pro-

cedure for flexion deformity of the wrist as well as pronation deformity. It has been found to be more useful than neurectomy of the pronator teres.

8. The operative results in those patients with quadriplegia were not as good as in the other groups. All patients who could not walk after being operated on were quadriplegic.

9. Certain general comments may be made regarding those operations in which the result was "poor":

(a) The majority of the "poor" results were in those who were feeble-minded or were in "motor status 1 or 2." In many the possibility of a "poor" result was considered prior to operation, but it was felt that an attempt should be made to give improvement. Certainly any error should be made in this direction rather than the other.

(b) The choice of procedure could be criticized in certain instances. Inattention to weakness in antagonistic muscles was a common mistake.

(c) Inadequate postoperative care and training were large factors in the "poor" group, in which the result should have been better. In this series, too brief immobilization in the corrected position was interpreted as the most frequent error in the postoperative regimen. We believe that intermittent support in the ideal position is desirable until the correction is stabilized, whether it requires months or years. The use of corrective casts at night should be a fundamental part of the routine.

The physical therapy during this period should emphasize, in addition to muscle training of the type usually prescribed in cerebral palsy, exercises to those specific muscles which oppose the deformity. Braces should be used if they are indicated, either as a temporary feature in establishing function or as a permanent measure if necessary.

ABSTRACT OF DISCUSSION

DR. BEVERIDGE H. MOORE, Chicago: This end result study has been excellently done. I have felt that these patients either improve a lot about the time of adolescence or they get a lot worse. The operations that my associates and I have used for these patients have been about the same as those of Drs. Green and McDermott. We do not do many tendon transplants in the muscles of the foot because in our hands they have not been very satisfactory. We prefer the arthrodesing operations; but one cannot do these until the patient has reached a certain stage of development in bone structure. During that interval we also do tendon lengthening, but we have been doing neurectomies of late and have thought that we were getting better results with them. We do them only as a matter of relaxing the muscles and do not use them if there is a structural shortening of the heel cord. The authors only accidentally mentioned one operation that we have found satisfactory and that is Durham's rotator section. We have seen a lot of improvement in the gait from the use of this simple operation. As for results in feeble-minded children, it has been and still is an open question in my mind whether it is worth while to operate on them; it is reasonably certain that we are not going to get a fair result.

DR. MANUEL E. PUSITZ, Topeka, Kan.: Surgery is but an incident in the treatment of cerebral palsy. Many failures can be traced to relying on surgical intervention and not on adequate follow-up. I was gratified to hear the authors stress postoperative splinting in these cases. One of the striking reasons for the reduplication of the operation is this lack of postoperative or, rather, postfixation support. I do not believe that the bad results are all in quadriplegias. Hemiplegias are more difficult to treat and offer the most difficult type of reconstructive problem. Surgery is merely a means to enable the physical therapist to apply his methods to train the patient. The object of tendon lengthening is to have the foot at a right angle so that the period of muscle training can begin early. I do not think that has been stressed enough. One must try as much as possible to simulate the normal tendency to learn to

walk at 2 and to speak at 5. By the time the child is 8 or 10 he has acquired a number of mental behavior patterns as well as motor defective mechanisms, which are very difficult to eradicate. A tendon lengthening in some of our cases is done as early as at 2 or 3, provided the patient does show evidence of a good mental status, and following the tendon lengthening a brace is applied for a prolonged period so that the physical educationalist can start in with those feet at right angles. The period of bracing may have to continue until such time as an arthrodesis operation may have to be performed, and, if the dorsal flexors by that time have not been developed, through some means these muscles can be made to act, and that forms part of our program in the muscle reeducation system. I have been amazed at the number of cases that show poor dorsal flexion action but if properly protected and properly braced will show a return of this motor power. If it does not then we do a triple arthrodesis; but the whole procedure is done as soon as possible to start the muscle education program, and surgical intervention is merely a step to that program.

DR. WILLIAM T. GREEN, Boston: I would agree heartily with Dr. Moore's comment that feeble-mindedness is a contraindication to operation provided he limits the statement to operations on the upper extremity. It seems to us that this does not apply to the lower extremity. If a patient who is unable to walk can be made to do so by an operation, it should be done despite the presence of feeble-mindedness. The ability to walk greatly simplifies the care of the patient even though he is dependent in other ways.

A CLINICAL ANALYSIS OF FIFTEEN THOUSAND CASES OF PNEUMONIA

AN EVALUATION OF THE EFFECTIVENESS OF VARIOUS THERAPEUTIC AGENTS

D. C. STAHLÉ, M.D.

Director, Division of Pneumonia Control, Commonwealth of Pennsylvania Department of Health
HARRISBURG, PA.

Pneumonia has for at least thirty centuries defied medical science to control its ravages in the human race and year after year continues to be a leading cause of death. Unfortunately, no satisfactory methods of prevention have been proposed. Isolation of infected patients and carriers and proper care of the common cold would help somewhat but gives little hope of any outstanding success. Prophylactic immunization recently has shown promise in preventing the disease or at least in modifying its severity if it is contracted. This procedure, however, is not yet practicable for general use. There must be a temporary resignation to the fact that annually one half million residents of the United States suffer from pneumonia. However, a great deal can be done about the 100,000 deaths resulting annually from this curable disease.

Recent advances in therapy have placed at the disposal of every physician facilities for treating his pneumonia patient. With their proper use the case fatality rate will fall from approximately 30 per cent¹ (the generally accepted figure in untreated pneumonia) to 10 per cent or less, the figure that can be achieved with the use of well directed specific treatment. Adequate

therapy, therefore, if given to all patients with pneumonia, will decrease the annual pneumonia deaths in the United States from 100,000 to 35,000, a saving of 65,000 lives.

The introduction of chemotherapy has made this possible, for there is now a specific therapeutic agent which is readily available and inexpensive and can be safely used by every physician on every susceptible pneumonia patient. Uniformly good results are assured.

A pneumonia control study was begun in 1937 in Pennsylvania as a cooperative endeavor of the state department of health and the state medical society. Laboratory facilities as well as specific therapeutic serum in certain types were made available to the private physician for use in treating indigent patients with pneumonia. From a modest beginning for the year from July 1, 1937 to June 30, 1938, when only 1,200 patients were treated, the program has expanded to include 9,000 patients given specific therapy for the same period in 1939-1940 and 10,000 for the nine months following July 1, 1940, with a steady decrease in the case fatality rate in the treated series. In the short space of three years 9,000 more patients have been brought under specific therapy, and therefore, transferred from the 30 per cent to the 10 per cent case fatality rate. This was accomplished by an extension of our program and the introduction of chemotherapy. The effects on the disease are reflected in the total state mortality figures, which for the years beginning July 1, 1937 were 7,117, 5,869 and 5,003,² and 160 fewer deaths were recorded in the first eight months (later statistics not yet available) of 1940-1941 than for the same period for the previous year.

When compared to 8,600 annual deaths from pneumonia in Pennsylvania, representing the average for the decade 1929-1938, and an all time low of 7,355 deaths in 1933, these figures would appear significant.

Careful records have been kept during the study, and my purpose in this paper is to present an evaluation of the various therapeutic agents used.

SOURCE OF MATERIAL AND ANALYSIS OF CASES

The series of cases comprising this study includes only those in which treatment was given in the interval between July 1, 1939 and April 1, 1941. In every case the clinical diagnosis was pneumonia, confirmed in 64.6 per cent of the series by roentgenograms or by recovery of a type specific pneumococcus from either the sputum or the blood. The case fatality rate in this group was 8.95 per cent. In the remainder of the series (5,341 cases), henceforth referred to as unspecified, there was no specific laboratory confirmation of the diagnosis; this group consisted of cases in which (1) more than one specific type pneumococcus was found; (2) pneumococci were found but could not be typed; (3) no pneumococci were found but other organisms, such as staphylococci, streptococci and *Klebsiella pneumoniae*, were present, and (4) no attempt was made to recover a causative organism. A case fatality rate of 9.64 per cent testifies to the severity of the illness in the group. Its inclusion adversely affects the series.

The cases presented are representative of pneumonia as it occurs in the general population in the low income levels. The series comprises cases of primary, secondary, postoperative, complicated and uncomplicated pneumonia and includes cases involving home treatment (representing 24.3 per cent of the series) and hospital

Mr. E. Douglas Burdick, assistant professor of statistics at the University of Pennsylvania, checked the statistical method used in this paper.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

This study was made by the Commonwealth of Pennsylvania Department of Health under Dr. John J. Shaw, secretary of health, in cooperation with the Pennsylvania State Medical Society.

1. Heffron, Roderick: Pneumonia with Special Reference to Pneumococcus. *Laboratory Pneumonia*. New York: Commonwealth Fund, 1939, p. 657.

2. Tentative figures offered at times are not yet available.

treatment (representing 75.7 per cent). All age groups are included and for convenience of analysis have been divided as follows:

Under 2 years of age, 12.8 per cent of the series; 2 to 12, 15.8 per cent; 13 to 60, 52.3 per cent; over 60, 14.7 per cent, and age not stated, 4.3 per cent.

TABLE 1.—*Mortality Rates from Pneumonia*
(July 1, 1939 to April 1, 1941)

Therapy	Number of Cases	Deaths	Case Fatality Rate, per Cent
Specific serum	181	27	14.92
Sulfapyridine	9,195	745	8.10
Sulfathiazole	3,666	304	8.29
Sulfadiazine	52	6	11.54
Serum and sulfapyridine	1,456	183	12.57
Serum and sulfathiazole	331	68	20.54
No specific therapy	370	69	18.65
Total	13,251	1,402	9.19

Obviously, any attempt to regiment cases in so large a series embracing such a widely scattered area was impossible. An evaluation of the merits of sulfathiazole versus sulfapyridine and of the drug (either of these agents) versus the drug plus serum, therefore, will necessitate a careful analysis of the many factors which affect the prognosis. These factors are (1) the type of pneumococcus acting as the causative agent, (2) the age of the patient, (3) the incidence of bacteremia, (4) the incidence of concurrent diseases (heart disease, cancer and conditions requiring surgical intervention), (5) the incidence of complications (empyema, meningitis and others) and (6) the interval between the onset of the disease and the beginning of therapy. Considered in the light of these various factors, certain deductions as to the effectiveness of these various agents in reducing the mortality from pneumonia should be possible.

It must be assumed that the group receiving combined therapy was a less favorable one than the group for which chemotherapy alone was used. In the past certain conditions—advanced age, bacteremia and the presence of preexisting systemic disease—have been used as indications for combined therapy, and if a larger percentage of patients receiving combined therapy have these conditions the case fatality rates for the group will be higher. Careful consideration must therefore be given these factors in evaluation. It is my purpose to learn whether patients coming under this adverse heading show better results with serum in addition to the drug and whether the presence of any of these factors is an indication for combined therapy.

An average dose of 123,000 units of serum per patient was given to patients who recovered and 155,000 units per patient to those who died.

RESULTS OF THERAPY

Gross Mortality (table 1).—That all therapeutic agents used in the study are effective in reducing anticipated deaths from pneumonia is apparent from the total case fatality rate of 9.19 per cent. The results for sulfapyridine and sulfathiazole, as others have found,³

are similar, and the difference is of no statistical significance. Of great interest are the fatality rates in the group treated with both a drug and serum. As has been the experience of others,⁴ the case fatality rate is higher in this group than in the group given chemotherapy alone. Undoubtedly the patients given combined therapy were more severely ill. A careful analysis of this series should reveal the reason and also establish indications for the use of combined therapy versus chemotherapy alone.

EFFECTS OF TYPE INCIDENCE ON CASE FATALITY RATES

That the severity of pneumonia varies from year to year is a generally accepted fact. Of great importance in this regard is the type distribution.

Table 2 shows the type incidence and the fatality rates among 6,043 specifically typed cases.

Types I, III and II, in the order given, were most frequent, accounting for 50.2 per cent of the series. Types VII, VIII and IV made up an additional 20 per cent, a total of 70.2 per cent of the total typed cases. The remainder or so-called "higher types" comprised 29.8 per cent. These results compare favorably with previous reports⁵ and indicate from type incidence alone that pneumococcal pneumonia occurring during the period of the study was of the usual variety and severity.

TABLE 2.—*Type Incidence of Pneumonia in Pennsylvania*

Type	Number of Cases	Percentage of Total	Number of Deaths	Mortality, per Cent
I	1,271	21.03	91	7.16

example, showing a rate of 16.3 per cent as compared to 7.2 per cent for those with type I. Obviously, therefore, any series having a predominance of cases due to an organism responsible for a high fatality rate would suffer accordingly.

From table 3 it may be seen that the distribution by type and unspecified cases is comparable for sulfapyridine and sulfathiazole. As would be expected, the types for which serum has been used in the past and has proved efficacious predominate in the combined series.

rate of 28.1 per cent for type I lobar pneumonia in adults, 36.6 per cent for type II and 46 per cent for type III, shows that all the agents used in this series are effective in reducing deaths from pneumonia.

INTERVAL BETWEEN ONSET OF DISEASE
AND BEGINNING OF THERAPY

Patients with pneumonia treated early in the disease have a much better chance to survive. Table 4 demonstrates the advantages of early therapy; a case fatality rate of 7.59 per cent was obtained when treatment was

* Only those cases in which accurate information was available in the groups discussed were included in this table.

If only typed cases are considered, the case fatality rate for patients given chemotherapy alone becomes 6.3 per cent as compared with 13.7 per cent for those given combined therapy. The preponderance of unspecified cases is disadvantageous to the former group. Interestingly, they are higher in each instance in the combined series. It is obvious that type alone is not the factor responsible for the higher rates. All other conditions being equal, there is no type of pneumonia for which serum should be given routinely in addition to a sulfonamide.

Comparison of the results in the present series with results tabulated by Heffron,⁶ in which there was a

begun within the first four days of the disease, as compared to 14.97 per cent, the case fatality rate after the fourth day.

The same ratio holds for the group that was given chemotherapy alone and the group given combined therapy.

Predominance of patients treated after the fourth day would give adverse results in any given series. The slight difference in the percentage of patients treated within four days is advantageous to the combined therapy group (84.96 per cent compared with 82.22 per cent for the chemotherapy group). This factor is certainly not responsible for the higher case fatality rate in the combined therapy group.

6. Heffron: Pneumonia, pp. 664-667, 670.

EFFECT OF CONCURRENT DISEASES ON
CASE FATALITY RATE

Any patient who has a serious illness in addition to pneumonia is at a definite disadvantage, and his chances of survival are appreciably less regardless of the therapeutic agent used.

In 25.38 per cent of the cases listed in table 5 there was at least one other condition coexistent with pneu-

13 to 60 and over 60, the results were similar for the two series, slightly advantageous to the combined therapy group.

Case fatality rates again are lower in the chemotherapy group. It is apparent, therefore, that concurrent disease is not the factor responsible for the higher death rate in the combined therapy group and is not alone an indication for the use of combined therapy.

* Totals include cases in which serum alone, sulfadiazine and other therapy was used

monia? The case fatality rate was 18.88 per cent, more than twice the rate in the overall series.

It is important to know what proportion of this series has been allocated to each type of therapy. The results again for sulfathiazole and sulfapyridine are comparable with an almost identical fatality rate in cases so complicated, 17.14 per cent as compared with 17.30 per cent. Only a slightly higher percentage of cases in the combined therapy group were complicated, 27.14 per cent as compared with 24.93 per cent. For the age groups

7 Concurrent diseases included pregnancy, puerperium, surgical intervention, heart disease, tuberculosis, diabetes, cancer and alcoholism

Of the deaths in the entire series, 52.01 per cent occurred in the group of patients having an associated illness in addition to pneumonia.

POSTPNEUMONIC COMPLICATIONS

The incidence of complications in the series was low and comparable for the sulfathiazole and the sulfapyridine treated patients and fairly so for the chemotherapy versus the combined therapy group. The former shows one or more complications in 9.31 per cent of the series; the latter shows 11.8 per cent. This slight difference can be anticipated on the basis of a

generally more severely ill group of patients in the combined therapy group, with probably a higher bacteremic incidence, which, as shown by Tilghman and Finland,⁸ definitely increased the expected complications.

The case fatality rate for those of the series showing a complication was 12.4 per cent if otitis media was included and 16.4 per cent if otitis media was excluded.

The case fatality rates were as high as or higher than 16.4 per cent in the combined therapy group for each complication except empyema.

Of especial interest are 82 cases of pneumococcal meningitis (not all secondary to pneumonia) with 67 deaths and a case fatality rate of 81.7 per cent. In spite of new developments in treatment, the fatality rate in this condition in our series was extremely high. Patients treated with the drug alone have fared as well as those in whom serum was used in addition.

2 years of age: 14.60 per cent as compared with 1.57 per cent for the combined therapy group; the latter, on the other hand, has a slightly higher percentage of patients over 60 (17.01 per cent as against 14.33 per cent for the drug alone group). The drug alone group gains a considerable advantage in having 17.7 per cent of the patients in the age group 2 to 12; whereas the combined therapy group has only 3.75 per cent in this age group. This advantage is offset somewhat by a predominance of cases in the favorable age group 13 to 60 years in the combined therapy group, 73.36 per cent as compared with 49.15 per cent.

Undoubtedly, the age distribution is somewhat unfavorable to the combined therapy group and is a factor in accounting for the higher case fatality rate in this group. It is interesting, however, that age group for age group the case fatality rates are lower in the

* Unspecified in the chemotherapy group includes cases in which a pneumococcus was recovered from the blood stream but not typed.

† The four bacteremic pneumonias included in the combined series occurred in cases in which the pneumococcus from the blood stream was not typed and two or more typed pneumococci were recovered from the sputum.

EFFECT OF AGE ON CASE FATALITY RATE

Pneumonia exacts a high toll at the two extremes of life.

Table 6 demonstrates my results to be in accord with this statement. Case fatality rates by age groups show 9.26 per cent for children under 2 years, 1.53 per cent for children from 2 to 12 years, 7.73 per cent for the group from 13 to 60 years, and 23.99 per cent for patients over 60 years. Obviously, therefore, any series showing a predominance of patients of the age group under 2 and over 60 would be penalized. A predominance of the age group 2 to 12 would be a distinct advantage.

The age group distribution for sulfathiazole and sulfa-pyridine are comparable, with comparable therapeutic effectiveness of each of the drugs within any age group. The drug alone versus the combined therapy group shows certain significant differences. The drug alone group has a decided predominance of patients under

drug alone than in the combined therapy group. These results do not confirm the statement that all patients over 40 should be treated with combined therapy. Obviously, many patients over 60 do just as well on the drug alone, and age itself is not an indication for combined therapy. Age distribution does not explain the discrepancy in the case fatality rates in the combined therapy versus the chemotherapy group. Some factor as yet not discussed must be present to account for this finding.

EFFECTS OF BACTEREMIA ON CASE FATALITY RATE

A severe test of the efficacy of any therapeutic agent is its effect on bacteremic pneumonias, for it is well known that the case fatality rate is from three to eight times as high as in an otherwise comparable series of nonbacteremic patients. Tilghman and Finland⁸ have shown in a large series of pneumonia patients, treated and untreated, a case fatality rate of 77.49 per cent in bacteremic as compared with 28.09 per cent in nonbacteremic patients. Our results are comparable since they show the same relationship to exist. In 376 bacteremic

8. Tilghman, R. C., and Finland, Maxwell. Clinical Significance of Bacteremia in Pneumococcal Pneumonia. Arch. Int. Med. 59:692 (April) 1937.

emic patients treated with either the drug alone or the drug combined with serum, the case fatality rate was 29.52 per cent as compared with 9.32 per cent in the nonbacteremic series. Obviously, again a group with a preponderance of cases showing this condition would suffer a severe penalty.

Quite by chance there were 188 patients with pneumococcic bacteremias in the combined therapy group and the same number in the chemotherapy group.

Table 7 presents a detailed breakdown of the bacteremic cases in the two groups. The case fatality rate in the combined therapy group is 31.9 per cent as compared with 27.13 per cent for the chemotherapy group. These results are comparable. The type distribution in the two groups shows no significant differences. The unspecified cases in the chemotherapy group tend to raise rather than lower the total case fatality rate.

Age distribution is almost identical for the two groups and age group for age group the case fatality rate is at least as low or lower in the chemotherapy group.

Complications of the disease and incidence of accompanying conditions or concurrent diseases, which previously have been shown to be important factors in prognosis, are comparable in the two groups.

Especially interesting are the results with type III organisms, which heretofore have been associated with an extremely high case fatality rate, 98.3 per cent in a series of 118 bacteremic cases reported by Tilghman and Finland.⁶ Fifty-two cases presented here show a fatality rate of 51.9 per cent, still a high rate but by comparison extremely low. An identical number of cases of type III pneumonia appear in each therapy group with a comparable distribution by age group. In every instance the fatality rates are as low or lower in the chemotherapy group. The percentage of cases associated with other illnesses as specified previously is identical.

Not shown in table 7 for the sake of simplicity is the effect of sulfathiazole and sulfapyridine on bacteremia. They were equally effective in controlling this condition. My results indicate that combined therapy is no more efficacious in bacteremic pneumonia than is the drug alone, and therefore its presence does not constitute an indication for drug and serum treatment.

A careful analysis of this series from the standpoint of the most important factors that can influence the prognosis in pneumonia has been made. A significant factor has not yet been found to account for the increased case fatality rate in the combined therapy group.

Certainly serum is not harmful in the treatment of pneumonia and, therefore, some reason for this difference must be present.

Bacteremia in pneumonia has been considered a prime indication for the use of combined therapy and, therefore, one should expect to find a much higher bacteremic incidence in the combined therapy group than in the chemotherapy group. Such is the case, for the combined therapy group shows bacteremia in 25.7 per cent of the cases in which culture was done as compared with 6.3 per cent for the chemotherapy group (table 8).

If one assumes that cases in which culture was done are representative of the combined therapy group and applies a correction factor to the chemotherapy group, making a hypothetical group with a comparable bacteremic incidence, then type for type, age group for age group, the case fatality rate becomes almost identical in the two therapy groups. Discrepancies as noted throughout the paper are eliminated and comparable

results in the two groups are now apparent. The major difference in the two groups is the bacteremic incidence. Since it has been shown that chemotherapy is as effective in this particular group of patients as in the group with combined treatment and that all other factors are relatively comparable, it would appear that the burden of proof of the advantages of combined therapy over the drug alone rests with those who advocate such treatment.⁹

UNTOWARD REACTIONS

The appraisal of the efficacy of any form of therapy must take into consideration the undesirable effects of the therapeutic agent itself. In this series severe toxic reactions of either of the chemotherapeutic agents have been infrequent and need not greatly concern the physician in making a choice of therapy for his pneumonia case.

As has been the experience of others,² vomiting has been less frequent and less severe with sulfathiazole than with sulfapyridine. Drug fevers and drug rashes were slightly more prevalent with the former. Anemia and leukopenia were less frequent among the patients treated with sulfathiazole.

Hematuria occurs with approximately equal frequency with the two types of treatment.

TABLE 8.—*Mortality in Relation to Blood Cultures*

	Positive Cultures			Percentage Positive	
	Cases	Deaths	Case Fatality Rate	Cases	Deaths
Chemotherapy.....	188	51	27.13	6.26	17.89
Combined therapy.....	188	60	31.91	23.68	42.86
Total.....	376	111	29.52	10.07	20.12

Three fatalities have been attributed to the use of the drug in 14,648 cases: One from exfoliative dermatitis following sulfathiazole therapy; one from obstructive uropathy and anuria following the use of sulfapyridine, and the third from leukopenia and acute agranulocytosis following the use of sulfapyridine.

Serum reactions were of the usual variety, frequency and severity in the series. One fatality was attributed to the serum used.

COMMENT

My concern in this paper has been an evaluation of specific therapeutic agents in the treatment of pneumonia. All agents reported herein have been effective in reducing pneumonia deaths.

From the material presented, it is apparent that the etiologic agent, the distribution of the pneumococcus type, the age of the patient, the presence of a complication of the disease, the presence of concurrent diseases, the interval between the onset of pneumonia and the beginning of therapy and the presence of bacteremia all exert a definite influence as to the ultimate outcome of the illness, regardless of the therapeutic agents used.

Little difference is demonstrable in the ability of sulfapyridine and sulfathiazole to influence the outcome of pneumonia under any circumstance. The case fatality rates in this series were comparable for the two drugs in a comparable group of cases. Sulfathiazole is probably the drug of choice, since vomiting, an undesirable side effect of chemotherapy, is encountered only half

9. The paper by Plummer and his associates (Chemotherapy versus Combined Chemotherapy and Serum, J. A. M. A. 116:2366 (May 24) 1941) read by the author after completion of this paper tends to confirm this impression.

as frequently as with sulfapyridine and is much less severe when it does occur. This is important to the practitioner, especially in his private practice. Drug fever and drug rash were more common with sulfathiazole; anemia and leukopenia were more common with sulfapyridine. Other toxic reactions were comparable. No difference was apparent in the relative influence of the two drugs on complications of the disease.

On the basis of experimental studies in animals and in vitro we were led to expect that a combination of serum and chemotherapy would be more efficacious than the drug alone. This finding is not substantiated in the series just presented. Our results do not confirm the generally accepted indications for serum therapy in addition to the drug.

At present I believe that the best method of therapy in susceptible pneumonia is that after collection of base line specimens (sputum and blood culture) sulfathiazole should be given. Patients who fail to respond to chemotherapy in from twenty-four to thirty-six hours should have serum in addition. Serum is of value in those cases in which untoward reactions from chemotherapy require its discontinuance early in the disease. Chemotherapy gives the best results when started early, and its use is indicated as soon as the diagnosis of pneumonia can be made.

Failures with any form of therapy still occur and are most frequent in infancy and old age, in patients treated late in the disease and in those with conditions complicated by other preexisting severe systemic illnesses. Less than 50 per cent of pneumonia deaths occur in otherwise healthy persons.

SUMMARY AND CONCLUSIONS

1. The case fatality rate in the series of 15,251 cases of pneumonia is 9.19 per cent. The vast majority of the patients were treated with sulfapyridine or sulfathiazole, either alone or combined with serum.

2. All specific therapeutic agents used demonstrated their ability to lower anticipated case fatality rates in any given group.

3. Sulfathiazole appears to be the chemotherapeutic agent of choice at the present time, showing an equal therapeutic effectiveness to sulfapyridine with fewer untoward reactions—particularly less vomiting.

4. No inclusive statement can be made as to any group of patients who should receive serum in addition to chemotherapy. The pneumococcus type alone, the age group alone, the bacteremias alone, or associated systemic diseases do not constitute an indication for combined therapy. Clinical judgment is essential, and for those patients extremely ill and in whom prompt recovery is necessary early combined therapy is probably indicated. Others should have serum in addition, if an early response to chemotherapy alone is not manifest or early toxic reactions require discontinuance of the drug.

5. Complications of the disease apparently are low in any specifically treated series of cases.

6. Severe toxic reactions of chemotherapy are infrequent and need not greatly influence the physician in choosing his therapeutic agent in pneumonia.

7. Early use of chemotherapy for best results should be stressed.

8. Sharp reductions in pneumonia deaths will result from extension of specific therapy to all susceptible pneumonia patients.

ABSTRACT OF DISCUSSION

DR. JOHN J. SHAW, Philadelphia: About three years ago the state of Pennsylvania inaugurated a new setup in pneumonia control programs. After careful planning and with the complete cooperation of the state medical society and its pneumonia commission the program began operation in the fall of 1939. It consisted in the establishment of one hundred and eighty pneumonia control stations conveniently located throughout the state. Each station was prepared to furnish the physician with serum in any type, sulfapyridine and any laboratory service necessary for proper diagnosis, or for observation of the patient while under therapy. Not knowing what therapeutic agent or combination of agents was most effective, all were made available. A public health education program augmented our pneumonia control efforts. Numerous educational talks were given to the lay groups, and many pneumonia symposiums were held in the county medical societies in order to bring every one up to date in the treatment of pneumonia. The first year of operation showed an overall case fatality rate of just over 10 per cent, which, when compared to the 35 per cent previously operative in untreated pneumonia, shows phenomenal progress. Pennsylvania in 1931 had the eighth highest death rate of any state in the United States; today it is forty-third. Complete team work between the state medical society and the state department of health insured the immediate success of this program. The results of our efforts have been described today by Dr. Stahl. Chemotherapy has made practical the treatment of the pneumonia patients at home. Ready accessibility and ease of administration will greatly increase the total number of cases coming under therapy. Ninety per cent of our pneumonia patients treated were hospitalized previous to 1939. In the past two years 50 per cent of them are being treated by their family physicians at home. The use of serum has gradually diminished since the advent of chemotherapy. On the surface this seemed to be a lamentable fact, but most recent material available shows no outstanding benefits for combined therapy over the drug alone. The experience of Pennsylvania's pneumonia program seems to concur with this impression. This program has proved conclusively that pneumonia mortality can be much reduced by giving adequate care to victims. Complete cooperation between organized medicine and public health medicine in pneumonia control programs will result in fewer pneumonia deaths.

DR. JESSE G. M. BULLOWA, New York: Dr. Stahl is to be congratulated on this analysis of a large group of patients; however, a fundamental requirement in statistical study is to make sure that the populations compared are essentially similar, and Dr. Stahl himself says that this has not been determined for his groups. There were probably many more less severely ill patients in the chemotherapy group than in the chemotherapy plus serum group, because it is probable that only the patients who were more severely stricken received serum and they received it when chemotherapy had failed, or very late in the disease or as a last resort. Accordingly, it is not fair to take the analysis at its face value and to conclude that serum plus chemotherapy was either without value or harmful. In my own smaller series, when chemotherapy and serum were given simultaneously the death rate was either the same as or lower than when only chemotherapy was given. One of the outstanding findings in Dr. Stahl's analysis is the difference in the death rate depending on the pneumococcus type in both series. Apparently this is evidence of the operation of immunity responses. Apparently chemotherapy only reduces the virulence of the invading pneumococcus so that the patient suffers from a milder disease of its specific type. With chemotherapy the usual general death rate is 8 or 9 per cent, which in part may be due to failure of the immunity mechanism in patients who die. They might have been saved by serum. By further analysis of his data Dr. Stahl may find a reliable evaluation of chemotherapy and chemotherapy plus serum, under various circumstances. It should be possible to compare the effect of the two therapies in early young patients, in early old patients, in late young patients and in late old patients. It should be determined whether the serum plus chemotherapy was given simultaneously or tandem or, as may have happened, largely

to moribund patients. There is no advantage in giving serum to patients whose own immunity has already secured recovery. These patients are not benefited by serum; they are going to recover in response to chemotherapy alone and swell the recovery in that group. Serum therapy reduced the gross mortality rate from pneumonia one half; chemotherapy reduced it another half. It is this quarter or some of it which may be benefited by the combination, adding augmented resistance to reduction of virulence.

DR. ADOLPH RUMREICH, Bethesda, Md.: Dr. Stahle's report emphasizes the desirability of a frequent evaluation of the various components of public health programs, and of prompt revision of such programs in the light of such studies and of technical advances in general. The Pennsylvania state program is impressive and undoubtedly has contributed to the reduction in recent years of the state's pneumonia mortality. It must be gratifying to Dr. Shaw to observe that the procedures pioneered in his state have recently been formally endorsed without essential changes by the National Research Council and adopted as prescribed routine in the army. The soundness of the program is attested by the change in Pennsylvania's relative rank in respect to pneumonia mortality, as pointed out by Dr. Shaw. This occurred in spite of the presence within the state borders of important segments of the two highest risk injuries; namely, steel manufacturing and coal mining. Unfortunately, most of the other states have not achieved a comparable improvement in this serious public health problem. Preliminary reports indicate that in 1940 more than ninety thousand persons died in the United States of pneumonia, a 14 per cent reduction over the year preceding the introduction of specific chemotherapy for pneumonia. This is far short of what we were led to expect and falls far short of realizing the potentialities of the weapons now at our disposal. Dr. Stahle has stated that one half of the deaths in his series were due to pneumonia without complicating disease. When we consider that his series embraces all age groups, and that probably over thirty thousand pneumonia deaths in the United States in 1940 were in the age group 15 to 64, we see that our complacency at present about the pneumonia problem is unjustified and that we have a long way to go before we can boast that all has been done that can be done to stop this serious waste of manpower.

DR. DALE C. STAHL, Harrisburg, Pa.: It must be admitted that a more severely ill group of patients were included in the series treated with combined therapy, and this report was presented with that supposition being stated. I do not advocate the complete discontinuance of specific antipneumococcus serum in the treatment of pneumonia. Certainly there are definite indications for its use, and the physician should be prepared to use serum should it become necessary. At the present time the importance of drug resistance is not known. There is no reason to believe that those patients whose infecting organism has developed a drug tolerance will not respond satisfactorily if specific antipneumococcus serum is given. As Dr. Bullowa points out, there are some patients who do not respond to drug therapy alone and with the added boost of specific serum might recover where otherwise they would not. It is extremely difficult, however, to say that any patient would have died had serum not been used or that any patient would have recovered had serum been used in addition to chemotherapy. Likewise, it is impossible to know what would have happened to the combined series group presented if the drug alone had been given or what might have happened to the series treated with the drug alone if combined therapy had been given. My purpose in this paper was to point out that too much serum is being given under the indications for combined therapy operative in the past. Dr. Bullowa mentioned that serum is often used on patients whose immunity mechanism has already done what the serum would do if given, and further administration is of no advantage. This series was presented to indicate what the results of therapy have been in a large group of patients. The final word with regard to the place of specific antipneumococcus serum in the treatment of pneumonia must come from groups working in carefully controlled clinics where all factors which are of importance in prognosis in pneumonia can be carefully evaluated.

ADYNAMIC ILEUS AND THERMAL INFLUENCES ON GASTRIC AND INTESTINAL MOTOR ACTIVITY

J. DEWEY BISGARD, M.D.

OMAHA

GUY M. MATSON, M.D.

DETROIT

AND

JEROME HIRSCHMANN, M.D.

LOS ANGELES

The terms adynamic ileus and paralytic ileus are used to designate a condition characterized by distention and relative inactivity of the bowel. As implied by the latter term, there prevails an opinion that the condition is the result of paralysis of the bowel. This is implied also in much that has been written, and there have been statements from sources of authority that intestinal motor activity is totally or virtually suspended for many hours or even days after abdominal operations. These opinions, as will be shown, are not supported by factual evidence, either clinical or experimental.

Fig. 1 (case 2).—Residual ileostomy following exteriorization resection of a gangrenous loop of the ileum. Apparatus for recording peristaltic activity. The tube emerging from the stoma connects an inflated balloon within the ileum to the U tube manometer. An identical tube and balloon are displayed on the sheet across the patient's thighs. Changes of pressure within the bowel are transmitted from the balloon to the ink writer through the U tube. The ink writer records the pressure changes on the kymographic drum. (Courtesy of Surgery, Gynecology and Obstetrics.)

As to clinical evidence, our interest in the subject was aroused by experiences with the Miller-Abbott tube. It was observed that this tube traveled down the small bowel as readily and rapidly in the patient with so-called paralytic ileus as in the patient with normal intestinal function. Obviously, for a state of paralysis this phenomenon presents an incongruous situation. For a logical explanation it must be assumed that in a state of ileus the stretching of the bowel wall from distention is in large measure responsible for the lack of motor activity. It is a well known fact that overstretched muscle loses much of its ability to contract. Furthermore, the function of the muscle is much impaired by the relative state of ischemia which results from the stretching of the blood vessels in the wall of the bowel. As the stretching is relieved by deflating the bowel through the indwelling tube, motor activity is promptly resumed. This we have verified by the flu-

Read before the Section on Surgery, General and Abdominal, at the Ninety-Second Annual Session of the American Medical Association, Cleveland, June 4, 1941.

roscopic examination of 2 patients who were given barium sulfate orally after the Miller-Abbott tube had traveled a few feet down the small bowel.

Another incongruous situation is observed in the relief of ileus which may follow the paralysis induced

Fig 2 (case 2).—Recordings made on the fourth and fifth postoperative days. The peristaltic contractions were infrequent although present and fairly vigorous. The application of ice packs to the abdominal wall increased the tonus of the bowel and the frequency and the amplitude of peristaltic contractions, hot packs inhibited motor activity, as did the ingestion of ice water orally, and hot water given orally stimulated motor activity. (Courtesy of Surgery, Gynecology and Obstetrics)

by spinal anesthesia. Here is presented the paradoxical situation of relieving paralysis by inducing paralysis. From this bit of evidence the probable mechanism of ileus may be conjectured. By inducing paralysis, spinal anesthesia presumably releases the inhibiting action of the dorsolumbar sympathetic nervous system on the motor activity of the bowel and leaves the vagus unopposed. It is probable, therefore, that ileus results, at least in part, from an imbalance between the antagonistic actions of the dual innervation of the bowel.

LA RECTUM—CAECOSTOMY—RESECTION

STRANGULATED UMBILICAL HERNIA

Fig 3—A (case 3), simultaneous recordings of the motor activity of the ileum through an inflated balloon passed orally and of the ascending colon through a balloon passed through a ceco-stomy stoma. Peristaltic activity was definitely present, although of subnormal vigor, thirty minutes after operation. By twelve hours the motor activity was in excess of normal. This evidence is not consistent with the theoretic statement that after an abdominal operation the bowel is totally inactive for many hours. B (case 4), a tracing made in a case in which adynamic ileus developed after reduction and repair of a strangulated umbilical hernia. Contractions, although feeble, are discernible. An effective dose of pitressin was followed promptly by a noticeable increase of tonus and of the amplitude and duration of peristaltic contractions.

Complete paralysis of the bowel does occur in the presence of diffuse or generalized peritonitis, and it is our opinion that the term paralytic ileus should be reserved for and applied only to this condition.

EXPERIMENTAL OBSERVATIONS

The motor activity of the stomach and the bowel is enormously influenced by many factors. Some of these, such as emotional influences, are difficult or impossible to control. For this reason, studies of motor activity are subject to gross errors of interpretation and from them conclusions can be drawn only in those instances in which controlled factors of influence repeatedly produce the same or consistent responses. With this as a criterion the following observations are reported.

As in some studies previously reported,¹ continuous kymographic recordings were made of gastric and intestinal motor activity. These recordings registered the variations in pressure exerted on indwelling compressible rubber balloons by the peristaltic contractions of the viscera studied. Variations of pressure on these inflated balloons were transmitted through the Miller-Abbott tubes to which they were attached and thence

Fig 4.—Tracings from a tube indwelling the distal loop of the jejunum after an anterior Polya operation, showing greatly diminished motor activity during the first three postoperative days. By the fifth day the motor activity was normal and by the seventh day hyperactive. Peristaltic contractions although feeble, were discernible at all times, beginning one hour after operation. Jejunal feedings in each instance increased motor activity.

through U tube manometers containing bromoform to ink writers which inscribed the records. The apparatus with a balloon in the ileum passed through an ileostomy stoma is shown in figure 1. For recording the activity of the large bowel the balloons were introduced through colostomy stomas, and for recording the activity of the stomach and of the small bowel they were introduced by means of nasoesophageal intubation.

ILEUS ASSOCIATED WITH PERITONITIS

Records were made in 2 cases of ileus associated with diffuse peritonitis. Brief histories follow.

CASE 1.—A man aged 66 came under observation with diffuse peritonitis, resulting from appendicitis, of four days' duration. Death ensued twenty-eight hours later. The nonoperative treatment instituted included the passing of a Miller-Abbott tube for the purpose of applying continuous suction. The tube passed through the pylorus and was observed through roentgenograms

1. Bisgard and Johnson.² Bisgard and Nye.³

to have passed some distance down the small bowel. Records made eighteen, twelve and six hours before death showed complete absence of motor activity.

CASE 2.—A man aged 26, critically ill with a strangulated internal hernia, a gangrenous loop of ileum and definitely established diffuse peritonitis, was operated on after one and one-half

The application of hot packs to the abdominal wall completely inhibited motor activity. Taking ice water by mouth likewise inhibited it, while ingestion of hot water increased it. These responses are shown in figure 2.

POSTOPERATIVE ILEUS

In previously reported studies² it was shown that the motor activity of the stomach and the bowel both during and after operation was influenced as much by the preoperative and postoperative medication and anesthesia as by operative trauma; also that the various anesthetics varied much in their effects on gastrointestinal motor activity. Ether, nitrous oxide and barbiturates have an inhibiting action, while spinal anesthetics, cyclopropane and avertin with amylene hydrate have either a stimulating effect or no appreciable effect.

Recordings of the activity of the bowel in 6 patients made during and at frequent intervals after clean and uncomplicated abdominal operations performed with one of the noninhibiting anesthetics at no time showed complete abolition of peristaltic activity and showed reduced activity for not more than twelve hours.

CASE 3.—A man aged 58 with an obstructing carcinoma of the rectosigmoid junction was relieved of obstruction by a cecostomy, and eight days later the rectum was resected in one stage with the patient under spinal anesthesia. The day

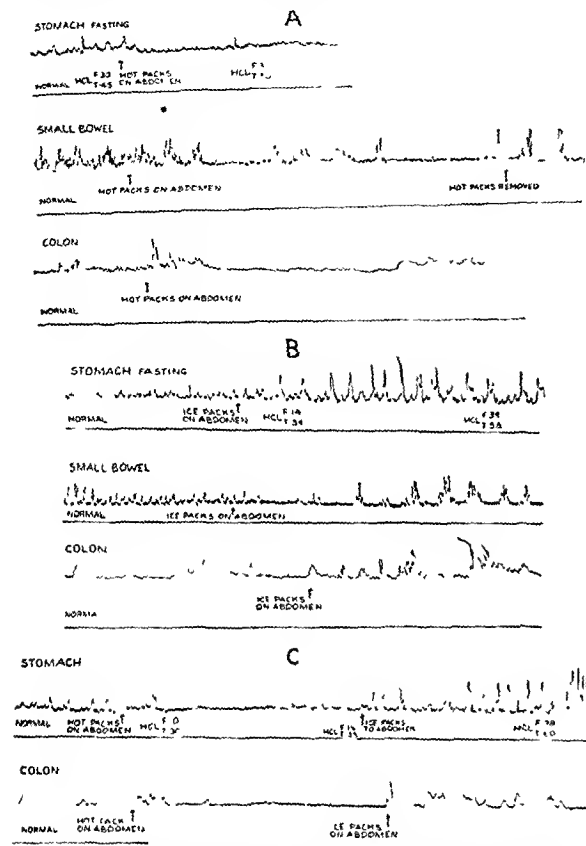

Fig. 5—A, recordings of motor activity of the stomach, the small bowel and the colon before and after covering of the abdominal wall with hot water bottles. After an interval of five to ten minutes, tonus became slightly diminished and peristalsis greatly inhibited in all three segments. The acidity of the gastric contents remained unchanged. B, the application of ice bags to the abdominal wall produced vigorous motor responses in the stomach, the small bowel and the colon, as indicated by an increase in tonus and in the amplitude and duration of contractions. These responses did not come on immediately but followed a latent interval varying from five to fifteen minutes. There was a big increase in gastric acidity. C, recordings of the effects on the stomach and the colon of following external hot applications with ice packs. Ice was applied immediately after removal of the hot packs. The inhibitory response to the hot applications was converted almost immediately to the motor response to cold. Furthermore, gastric acidity remained unchanged during the application of heat and increased greatly after the application of ice. (Courtesy of Surgery, Gynecology and Obstetrics.)

hours had been devoted to intravenous hydration therapy, a blood transfusion and continuous gastric suction. At operation the gangrenous loop was exteriorized and resected between clamps, the two ends being left as ileostomy stomas. The proximal clamp was removed after forty-eight hours, and recordings through this stoma were made daily. For two days there was no evidence of motor activity. On the fourth postoperative day the pulse rate was much reduced and the abdomen much softer and, in keeping with this evidence of resolution of peritonitis, fairly vigorous though infrequent peristaltic contractions were recorded. On that day and the following one the records displayed in figure 2 were obtained.

Since it had been observed in the studies mentioned¹ that the normal bowel made definite responses to thermal influences it was decided to test the response of this infirm bowel to the same agents. As in the normal bowel, the application of ice packs to the abdominal wall caused a prompt increase in tonus and in the frequency and amplitude of peristaltic contractions.

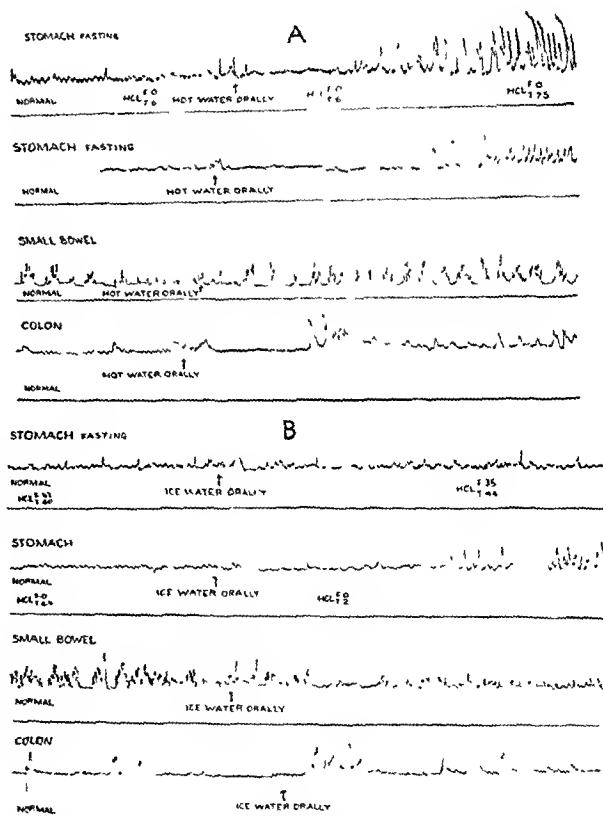

Fig. 6—A, hot water taken by mouth caused a vigorous motor response in the stomach and definite but less vigorous stimulation of the small bowel and the colon. The periods of increased activity were preceded by intervals of inhibition lasting from five to twenty minutes. B, the administration of ice water by mouth had little or no effect on gastrointestinal activity. Gastric acidity was decreased, as a result, presumably, of both dilution and inhibition. (Courtesy of Surgery, Gynecology and Obstetrics.)

before the resection was done a Miller-Abbott tube with a balloon had been introduced and carried into the ileum. A second balloon was threaded into the ascending colon through

2. Bisgard, J. D., and Johnson, E. K. The Influence of Certain Drugs and Anesthetics on Gastrointestinal Tone and Motility, *Ann. Surg.* 110: 802 (Nov.) 1939.

the cecostomy stoma immediately after operation, and recordings of the activity of the ileum and of the colon were made simultaneously. In recordings made thirty minutes and three hours after operation, motor activity, although of subnormal vigor, was definitely apparent. Twelve hours after operation and thereafter both ileum and colon showed activity in excess of normal. Two of these recordings appear in figure 3A.

While these studies were being carried out only 1 patient with uncomplicated and obstinately adynamic postoperative ileus was available for study:

CASE 4.—An obese woman aged 52 was operated on to relieve strangulation of a long loop of the ileum in an umbilical hernia. An alarming degree of distention developed fifty-two hours after operation, despite the application of constant suction through a Miller-Abbott tube in the proximal portion of the small bowel. This tube, which had been passed into the stomach before operation, was threaded through the pylorus into the jejunum at operation. Repeated enemas and 2 minim (0.1 cc.) doses of pitressin gave meager results. Finally a copious evacuation with a satisfactory diminution of distention followed the application of hot packs to the abdominal wall and the administration of 1 cc. of pitressin.

Records made during this period showed rhythmic peristaltic contraction to be present, though it was feeble. After the administration of the small doses of pitressin there was a slight increase in tonus and in the duration and amplitude of the

Fig. 7.—Ice packs applied to two thighs increased both gastric acidity and motor activity of the stomach. The ileum and the colon showed no definite or consistent response. (Courtesy of Surgery, Gynecology and Obstetrics.)

segmental contractions. After the large effective dose there was a big increase in tonus and in the amplitude and duration of peristaltic contractions, as shown in figure 3B. Obviously the muscularis of the bowel in this case was capable of vigorous contraction when effectively released from inhibition and stimulation.

In 2 cases the motor activity of the proximal portion of the jejunum immediately following gastrojejunal anastomosis was studied. In both cases an anterior Polya operation had been performed; in one a gastric carcinoma was resected and in the other a gastric ulcer. In each case, after the anastomosis had been completed the ballooned tip of the Miller-Abbott tube which had been passed into the stomach previously was threaded through the stoma into the distal loop of the jejunum for a distance of 10 or 12 inches (25 or 30 cm.). A second (Levin) tube, introduced into the stomach through a gastrostomy opening in the stump, was also threaded through the stoma and down the distal loop of the jejunum for a distance of approximately 16 inches (40.6 cm.). Through this tube hourly jejunal feedings were administered, being begun immediately after operation. Records of motor activity of the jejunum were obtained by means of the inflated balloon placed just proximal to the point where the feedings were delivered. The records (fig. 4) showed that the motor activity, which was barely perceptible one hour after operation and increased but feeble two hours

later, was fairly active within nine hours, normal in five days and hyperactive seven days after operation. Immediately after each feeding there was an increase in tonus and peristaltic activity.

An adequate explanation for the failure of a prompt return of normal motor activity in the foregoing 2 cases is not immediately apparent. There is good reason to believe that both the vagus and the sympathetic innervation of the bowel were much disturbed during the execution of gastric resection. There is also a theory that the stomach acts as a 'pacemaker' for much of the intestinal tract.

THERMAL INFLUENCES

A detailed account of the influence of hot and cold applications on gastric and intestinal motor activity and on the secretion of hydrochloric acid was made in a previous communication.³ A brief summary of these data follows. After establishing for each patient studied reasonably normal tracings from balloons indwelling the stomach and the small and the large bowel the following influences were brought to bear at successive periods of observation: (1) The abdominal wall was completely covered with hot water bottles for thirty minutes, (2) the abdominal wall was covered with ice bags for thirty minutes, (3) both thighs were covered with hot water bottles for thirty minutes, (4) both thighs were covered with ice bags for thirty minutes, (5) hot water was administered orally and (6) ice water was administered orally. During the period of recording the motor activity of the stomach, samples of the gastric content were aspirated and analyzed for acidity.

Complete series of records were obtained of responses of the stomach in 8 patients, of the small bowel in 6 and of the colon in 4. The responses were sufficiently consistent to be reported collectively as typical of the organ and the experimental factor. Heat applied to the abdominal wall inhibited motor activity of the stomach, the small bowel and the colon (fig. 5). Conversely, cold stimulated tonus and peristaltic activity. When heat or cold was applied directly to the wall of the stomach by having the patient drink hot or cold water the responses were reversed. Heat stimulated and cold had a slightly inhibiting effect on both gastric and intestinal motor activity (fig. 6). Hot applications on the thighs had no effect, and cold ones influenced only the stomach, producing a moderate motor response (fig. 7). Cold applications on both abdominal wall and thighs caused a big increase in both free and total hydrochloric acid.

From the physiologic data mentioned there may be obtained some guidance for the proper clinical uses of hot and cold applications. If it is beneficial, as is generally believed, to inhibit the motor activity of the gastrointestinal tract and thereby place it at rest as far as possible in the presence of inflammatory lesions, such as appendicitis and peritonitis, and of bleeding lesions, such as bleeding peptic ulcer, then hot applications and not ice bags are indicated. In the case of peptic ulcer the increase in gastric acidity following cold application to the abdominal wall also is undesirable.

During the past two years we have lavaged the stomach with ice water in 4 cases of actively bleeding ulcer. Either because of or in spite of this therapy the bleeding promptly ceased in 3 cases. Theoretically, direct chilling of the wall of the stomach should produce vasoconstriction (of bleeding vessels) in addition to lowering acidity and inhibiting motor activity.

3. Bisgard, J. D., and Nye, Dan: The Influence of Hot and Cold Application on Gastric and Intestinal Motor Activity, *Surg., Gynec. & Obst.* 71: 172 (Aug.) 1940.

The increase in gastric acidity which follows chilling of the body surface may explain the recurrence of peptic ulcer in the fall and the spring, when there are rapid and radical changes in temperature.

Throughout this discussion the term motor activity has been used and the term motility avoided. The records measured only peristaltic activity and tonus. Motility refers to the movement of gastric and intestinal contents, and this is dependent not only on peristalsis but on the patency of the sphincters and on coordinated activity between adjacent segments of the stomach or the bowel. Peristalsis is ineffectual when disorganized. In the normal process of both segmental and mass movements of intestinal contents the various segments of the bowel contract and relax alternately in well integrated fashion. As a given segment contracts and expels its contents the adjoining distal segment relaxes to receive it. Failure of this distal segment to relax not only interferes with the normal movement of intestinal contents but gives rise to cramplike pain, such as colic and gas pain. Hot applications are more effective than cold ones in relieving gastrointestinal cramps, because their inhibiting effect relaxes spasm and thereby facilitates coordinated activity.

In regard to the first fluids taken by mouth by patients after operation, we have observed no difference in the response to cool and to warm fluids except that cool ones are more palatable. Ice water, however, is definitely less well tolerated.

1418 Medical Arts Building.

ABSTRACT OF DISCUSSION

DR. JAMES M. WINFIELD, Detroit: With regard to the concept that the term "paralytic ileus" should be reserved for cases of peritonitis, I disagree with Dr. Bisgard and his co-workers. I have found that the balloon tipped long tube progresses satisfactorily in the presence of ileus associated with peritonitis, and accordingly the term denoting paralysis is not correct. I prefer to call ileus associated with peritonitis "patent inactive ileus" or "adynamic ileus." The relief of distention permits the bowel to become active, even though its entire power is not present. In the presence of ileus the use of heat either by packs or by a light cradle, in conjunction with tube decompression, not only may affect motor activity but, as Mueller has pointed out, may favor a more rapid and efficient return of blood supply to the impaired intestine. I do not favor the use of pitressin for effect on the small bowel, as it is questionable just how much influence this drug has on the jejunum and ileum, the large bowel primarily being stimulated. As to the effect of heat and cold applied externally to the abdomen, it is interesting to note that heat has been used in the presence of intra-abdominal infection for years in numerous clinics. No doubt the beneficial effect noted may be explained by the findings of the authors that external heat decreases gastrointestinal motor activity. As was mentioned in the paper, the delayed return of motor activity following gastric resection was notable and it was stated that this may be due to the fact that the stomach, in the role of a pacemaker for the intestinal tract, was profoundly affected. In some bile experiments on human beings, although the stomach showed some stimulated motor response to bile, the intestinal tract as a whole gives evidence of a considerable decrease in emptying time. Thus it is quite possible that the stomach partially initiates the effectual and coordinated intestinal activity. Also it is well known that the drinking of warm fluids favors evacuation of the bowel. Many of the points brought out in the paper have a direct application to clinical practice.

DR. CHARLES W. MAYO, Rochester, Minn.: In these days of costly therapeutic measures it is refreshing to hear a paper on an inexpensive one—a paper which demonstrates that it is not the degree of cost which is the gage of efficacy of a therapeutic measure but rather its judicious use. I was interested

to hear that cold on the abdominal wall or thighs caused large increases in free and total hydrochloric acid; that external temperature therefore may be the cause of exacerbation of duodenal ulcer in the spring and fall. Although it is true that heat and cold may be contributing factors, I believe one which is even more basically sound is that variation in water intake from the heat of the summer to the cold of the winter is of greater influence on gastric acidity, on the basis of dilution. We are familiar with the synergistic action of certain drugs, such as pitressin and morphine, on the small and large bowel; yet in this presented work there is no evidence that heat and cold have such synergy in relation to the small or large bowel. Believing in the law that for every action there is an opposite and equal reaction, I am prompted to the question What was the duration of the experiment of the application of heat and cold to the abdomen? For instance, if heat applied externally gives an initial quieting effect, might it not give, if continued, a stimulating effect, the time of the opposite action being an individual variable? It would seem that hibernation and quiescence might be possible examples of the effect of continued cold on intestinal peristalsis.

DR. J. DEWEY BISGARD, Omaha: In answer to Dr. Mayo's question, we did try to determine how long the effect of the thermal agents lasted and found that it lasted about an hour, as a rule. However, if after an interval a reapplication was made there was again a response but of a somewhat lesser degree.

"COLI METABOLIN" THERAPY IN HAY FEVER

PSYCHOGENIC BENEFITS

MARY HEWITT LOVELESS, M.D.

AND

HORACE S. BALDWIN, M.D.

NEW YORK

This investigation tests the recent assertion by Elsbach¹ that metabolic products of the colon bacillus have therapeutic value at least equal to that of specific inoculations in allergy. Elsbach reported that 70 per cent of his hay fever group were "cured" and another 28 per cent improved as the result of some nine inoculations of Coli Metabolin (Tosse). He held that this filtrate of *Escherichia coli* exerts a "desensitizing" influence through the sympathetic nervous system, obviates the need for diagnostic tests and preseasonal treatments and frequently affords relief after the second or third dose.

METHODS AND MATERIALS

After investigating the manufacturing process of Coli Metabolin (Tosse), and finding no contraindication to its use, we treated 20 ragweed-sensitive patients with the product.² Most of the courses were begun during the last week of August, the earliest being instituted on Aug. 22, the latest on Sept. 5, 1941. Although the subjects continued to make frequent visits for injections and observation until after October 1, so sharp a decline occurred in the atmospheric pollen content after September 20 (table 1) that clinical information collected after this date was disregarded.

The general plan was to give each patient 2 cc. of Metabolin under the skin daily until five or more doses had been taken or relief of symptoms occurred. As many as twelve consecutive injections were given at daily intervals in some instances. After the initial series

of daily injections, Metabolin was administered every one to three days. On the intervening days the patients received physiologic solution of sodium chloride in lieu of the metabolites or else were given no treatment at all. It was hoped thereby to evaluate the psychogenic effect of inoculation per se and to make due allowance for remissions, which occur spontaneously in hay fever.

Each patient kept a daily record of symptoms in terms of slight, moderate and severe hay fever and/or asthma. As a preliminary to statistical analysis, the data obtained from all subjects during the thirty day experimental period were segregated into four groups according to the relative height of the pollen count. Data pertaining to days on which there was little pollen in the air (twenty grains or less per cubic yard) were assigned to the first quartile. Observations which applied to days of increasingly high pollen count were allotted to the second, third and fourth quartiles, respectively, as shown in table 2. Data belonging to each quartile were then classified according to the patient's clinical response to the three conditions of treatment (Metabolin, physiologic solution of sodium chloride and no injection). The frequency with which symptoms were completely relieved, partially relieved, unaltered or made worse in relation to the three types of therapy has been recorded in tables 2 and 3. Finally, comparisons were made between the various sets of figures, differences being tested for significance by means of the chi square and probability (P) values.³ Sheppard's modification² was employed to increase the accuracy of

or 23 per cent, of all Metabolin injections were followed by complete disappearance of symptoms within an hour. An equally good effect was obtained after eighteen, or 26 per cent, of the sixty-nine inoculations of physiologic solution of sodium chloride. When the

chi square and P values were determined, this difference between Metabolin and saline therapy was found to be of no significance, as table 4 A shows. This situation obtained in each of the quartiles of pollen count and in all quartiles combined. Of one hundred and thirty-five occasions when no therapy was given, fourteen, or 10 per cent, were associated with symptom-free periods which occurred spontaneously during the hours following the customary time of inoculation.

Duration: The relief was comparable in duration regardless of which inoculum was involved, one to seventeen hours being the range observed for each. In the case of Metabolin, the mean duration of relief following the forty-five efficacious inoculations was six and four-tenths hours as indicated by table 3, the average for all one hundred and ninety-eight Metabolin injections being only one and four-tenths hours. A slightly more lasting relief was associated with the eighteen beneficial saline injections, seven and three-tenths being the average number of hours which elapsed before symptoms returned. The average duration of relief for all saline solution inoculations given was one and nine-tenths hours per injection. The average duration of spontaneous remissions which occurred on days of no therapy was found to be six hours, a figure closely approximating that found for Metabolin and for saline inoculations.

Partial Relief.—Incidence: Tables 2 and 3 list a total of thirty-five occasions when Metabolin produced partial

the chi square test when the number of observations used for comparison was small (ten or less). Values of P which were greater than 0.05 have been regarded as of no statistical significance.

FINDINGS

Complete Relief.—Incidence: Table 3 shows that forty-five of a total of one hundred and ninety-eight,

3. Fisher, R. A.: Statistical Methods for Research Workers, London, Oliver & Boyd, 1932

relief within an hour, roughly 17 per cent of all metabolite injections thus being followed by partial improvement. In the case of saline injections, this percentage was 16, an almost identical incidence. The chi square and P values (table 4 B) showed clearly that no significance could be attached to these differences in incidence. Partial relief was noted after the customary hour of inoculation on 6 per cent of treatment-free occasions.

Failure to Alter Clinical Course.—Symptoms continued unaltered after approximately half of the Metabolin injections given and after 58 per cent of the control inoculations (table 3). When the chi square and corresponding P values were determined, the difference between the metabolite and control solutions in this respect was not found significant (table 4 C). When, however, the combined figures for the two types of inoculum were compared with that for days when no treatment had been given, a decidedly higher incidence of unchanged symptoms were found for treatment-free occasions (82 per cent, as shown in table 3). This suggested that inoculation per se altered the trend of symptoms. In order to determine in what direction the act of inoculation altered the intensity of hay fever, further comparisons were made.

INFLUENCE OF INOCULATION PER SE

Complete relief occurred after 23.6 per cent of inoculations of both types, whereas spontaneous remissions were noted on only 10 per cent of all treatment-free days. Most of the latter fell in the first quartile, when the atmospheric pollen was at low concentration. The chi square and P values determined for the second and third quartiles showed that complete relief followed inoculations significantly more often than it occurred on days of no therapy. Although this was not the case for the first and fourth quartiles, analysis of the combined data from all quartiles revealed that remissions were definitely increased in frequency if some inoculation had been given (table 4 D).

When the incidence of partial relief was studied, 17 per cent of all inoculations were found to produce this result, whereas only 6 per cent of treatment-free days

TABLE 3.—Frequency with Which Various Clinical Results Occurred Following Inoculation of Metabolin, Physiologic Solution of Sodium Chloride and on Treatment-Free Days

	Metabolin			Saline Solution			No Treatment		
	In stances	%	Hr	In stances	%	Hr	In stances	%	Hr
Complete relief	43	22.7	6.4	18	26	7.3	14	10.7	6
Partial relief	5	17.6		11	16		8	5.9	
No change	98	49.4		40	55		111	82.2	
Worse	20	10.1		0			2	1.48	
Total	198	99.8		69	100		125	99.97	

showed the spontaneous occurrence of partial improvement. In a few instances (10 per cent) the allergic symptoms were made worse by Metabolin inoculations. Exacerbation of symptoms after the usual injection hour was noted on 1.5 per cent of the occasions when no treatment was given but was not observed in relation to saline injections.

On the whole, inoculation per se appeared to benefit the allergic patients, approximately 40 per cent of all

injections of either Metabolin or physiologic solution of sodium chloride being followed by partial or complete disappearance of symptoms, whereas similar relief appeared spontaneously in only 16 per cent of the treatment-free days.

TABLE 4.—Significance* of Difference in Incidence of Various Clinical Results Following Metabolin, Physiologic Solution of Sodium Chloride and No Inoculation

	Pollen per Cu. Yd. of Air	Chi Square	P	Difference in Incidence
Test A—Incidence of complete relief after Metabolin compared with incidence after physiologic solution of sodium chloride	5 to 20	3.28	>0.05	Not significant
	22 to 37	0.861	>0.3	Not significant
	63 to 126	0.645	>0.7	Definitely not significant
	144 to 332	0.056	>0.7	Definitely not significant
Test B—Incidence of partial relief after Metabolin compared with incidence after physiologic solution of sodium chloride	5 to 332	4.874	0.3	Definitely not significant
	5 to 332	0.146	0.7	Definitely not significant
	5 to 332	1.25	>0.2	Definitely not significant
	5 to 332	0.416	>0.5	Not significant
Test C—Incidence of unchanged symptoms after Metabolin compared with incidence after physiologic solution of sodium chloride	22 to 57	4.27	About 0.04	Significant
	63 to 126	56.73	<0.01	Definitely significant
	144 to 332	0.7	>0.3	Not significant
	5 to 332	41.76	<0.01	Definitely significant

* Determined by obtaining the chi square and P (probability) values

SUMMARY AND CONCLUSIONS

The claim of Elsbach that Coli Metabolin therapy is preferable to the usual antigen inoculation treatment of hay fever could not be substantiated. Although a degree of short lived improvement was observed among 20 ragweed-sensitive patients given an average of nine inoculations of Metabolin, a "cure" resulted in no instance and the transient benefits were duplicated both in degree and in duration by injections of physiologic solution of sodium chloride. Since the incidence of improvement was significantly greater when either solution was injected than when no treatment at all was given, it was concluded that the benefits of Metabolin therapy are of psychic rather than pharmacologic origin. We feel that there is no valid place for Coli Metabolin in the therapy of hay fever.

Chemical Elements.—Eighty-eight chemical elements have been isolated. Their separation by chemical means is sometimes easy, sometimes very difficult, and the best available tests differ greatly in sensitivity. Spectroscopic analysis provides a test for all constituents at once; but these tests too are unequally sensitive. Fortunately the two methods supplement each other. The composition of the earth's crust—above an arbitrary depth, such as ten miles—is well known. Oxygen is the most abundant element, whether by weight or by number of atoms. Silicon is next and then aluminum, iron, magnesium, calcium, sodium and potassium. These eight elements account for 98 per cent of the whole mass.—Russell, Henry N.: *The Cosmical Abundance of the Elements*, *Nature*, Nov. 29, 1941

Clinical Notes, Suggestions and New Instruments

ABERRANT PANCREATIC TISSUE WITH HYPERINSULINISM

FREDERICK GOETHE SMITH, M.D., MARION, OHIO

Aberrant pancreatic tissue was first observed by Klob in 1859. Faust and Mudgett¹ have recently reviewed the reported cases and added 1 of their own, bringing the total to 370. Apparently, through some error in embryologic development, pancreatic tissue may develop in various ectopic sites separate from the normal pancreatic anlage. It has been found most frequently in the stomach, duodenum and jejunum, fairly often in the ileum and Meckel's diverticulum and rarely in the gallbladder, omentum and mesentery.

Seldom of clinical importance, the gland tissue is usually an incidental finding at surgical intervention or autopsy. It may, however, be the site of inflammation and ulceration necessitating surgical removal, and in the ileum the condition has been responsible for intussusception. Roentgenologically it may produce a filling defect simulating a polyp or a malignant growth. The case to be reported is of interest in exhibiting definite symptoms of hyperinsulinism which were relieved by the surgical removal from the wall of the duodenum of a nodule of aberrant pancreatic tissue.

History.—Mrs. E. R., white, a housewife aged 45, was first seen Jan. 16, 1940. Her family history was irrelevant. She had had the usual children's diseases and at 30 years had scarlet fever and rheumatism and was confined to bed for the better part of a year. She was subject to urticaria produced by eating asparagus. At 27 her appendix was removed and at 29 a tonsillectomy was done.

The patient had not been well for twelve or fifteen years. She had been treated by many different physicians for a variety of complaints including sinus infection, "dropped stomach," sick headaches, cystitis, nervousness and "menopause." In 1935 examination revealed a slightly enlarged right kidney pelvis and mild secondary anemia; the anemia responded well to Bland's mass and diet. Since then she received a great deal of theelin, liver extract and vitamins. Five months previous to my first examination she was given high voltage roentgen therapy over the pelvis for a persistent menorrhagia, which resulted in complete cessation of the menses.

At the time of her examination her chief complaint was weakness, which was so pronounced that she was unable to remain out of bed for more than a couple of hours at a time. If she stayed up a little too long she would tremble all over and become breathless. Sometimes she would feel faint, but she never lost consciousness and never had a convulsion. Her appetite was good and she occasionally ate between meals; some-

Fig. 1.—Dextrose tolerance test: Preoperative and postoperative response of the blood sugar to the ingestion of 75 Gm. of dextrose.

times she would awaken at night and eat. The only complaint of pain was a dull aching in the right flank posteriorly a little lateral to the costovertebral angle. There was some frequency and nocturia, and once or twice she thought that there was a little blood in her urine.

1. Faust, D. B., and Mudgett, C. S.: Aberrant Pancreas, with Review of the Literature and Report of Case, *Ann. Int. Med.* 14: 717-729 (Oct.) 1940.

Physical Examination.—The patient was rather poorly nourished, of asthenic habitus, subject to storms of emotional instability and depression but on the whole sincere and cooperative. She was 63¾ inches (162 cm.) tall and weighed 105½ pounds (48.3 Kg.). General physical examination did not reveal anything of importance.

Cystoscopy and retrograde pyelography demonstrated a mild trigonitis and a slightly enlarged right kidney pelvis with a descent of 2.5 cm. of the right kidney in the upright position. Comparison with roentgenograms made elsewhere in 1935 did not reveal any change.

Fig. 2.—Diagrammatic illustration of the appearance of nodule of aberrant pancreatic tissue on the descending portion of the duodenum as seen at operation.

Fluoroscopy of the chest did not reveal any abnormality; barium meal showed normal filling and function of the gastrointestinal tract. Abnormality of the duodenum was not observed. A barium enema showed normal filling of the large bowel. Intravenous cholecystography demonstrated a normally functioning gallbladder.

Laboratory examination of the blood, urine, serum Wassermann and gastric contents was essentially normal. The basal metabolic rate was -13. The electrocardiogram was normal and the dimensions of the sella turcica were normal.

A dextrose tolerance test was made employing 75 Gm. of dextrose orally; the blood sugar rose in two hours from a fasting level of 77 mg. to 181 mg. and then fell sharply to 37 mg. at the end of four hours. At this time the patient was extremely weak, perspired freely and trembled. She asked for something to eat and was given a slice of toast, with relief of symptoms.

The patient was observed over a period of several weeks; frequent carbohydrate feedings were necessary to relieve the symptoms of weakness. An attempt was made to give all the carbohydrate in slowly assimilated starches and to feed principally fats and proteins, but this was only partially successful because of the patient's craving for sweets. Numerous blood sugar determinations were made, usually two or three hours after meals, with a finding of consistently low levels, ranging from 61 to 77 mg. per hundred cubic centimeters of blood. The only measure that afforded any significant relief from the extreme weakness was the frequent administration of food, and at one time she was taking as many as eleven meals in twenty-four hours. On the basis of the hypoglycemia, without demonstrable extrapancreatic cause, surgical exploration of the pancreas for a possible adenoma was advised.

On March 4 the patient was subjected to laparotomy. The abdominal and pelvic viscera were normal to palpation. The pancreas was exposed and its substance carefully palpated but nothing abnormal was found. It was then noted that on the descending portion of the duodenum just below the superior duodenal flexure there was a nodule under the serosa which resembled pancreatic tissue. The peritoneum was incised over this nodule and it was carefully dissected free, exposing the

putting outer surface of the still intact duodenal mucosa. All bleeding points were carefully ligated and the defect was closed with a double row of Lembert sutures. The abdominal wall was closed in layers in the usual manner.

The postoperative course was uneventful and the patient was discharged to her home on the twelfth postoperative day. Her progress to date has been satisfactory. The weakness of which she formerly complained is much relieved, she has gained 20 pounds (9 Kg.) and she no longer requires frequent feedings. Her dextrose tolerance curve appears to have been somewhat altered, no longer reaching such high early levels but nevertheless dropping to 62 mg. at four hours (fig. 1). The readings are given in the accompanying table.

Dextrose Tolerance Test: Response of the Blood Sugar to the Ingestion of 75 Gm. of Dextrose

Time	Blood Sugar, Mg. per 100 Cc. of Blood		
	Preoperative		Postoperative
	1/19/40	2/28/40	9/24/40
Fasting	77	100	79
30 minutes	77	128	129
1 hour	166	210	111
2 hours	181	171	85
3 hours	100	85	82
4 hours	37*	69	62

* Accompanied by symptoms of insulin shock.

Fig. 3.—Section through aberrant nodule showing apparently normal acinous tissue separated by broad strands of fibrous connective tissue (hematoxylin and eosin stain; reduced from a photomicrograph with a magnification of 120 diameters).

Pathologic Examination.—The tissue removed consisted of a small oval flattened piece of yellowish white tissue with the gross lobular markings of pancreas. It measured approximately 2 by 1.5 by 0.5 cm. and weighed 1.5 Gm. Grossly the cut surface was yellowish white and lobulated and appeared to be normal

pancreatic tissue. Microscopic examination showed pancreatic tissue consisting of acini and ducts, with a few well circumscribed islets and numerous diffuse groups of islet cells (figs. 3 and 4).²

COMMENT

Certainly one must be careful in the evaluation of clinical observations of this sort. The removal of so small a quantity

Fig. 4.—High magnification of the aberrant pancreatic tissue, showing diffusely scattered areas of islet cells between the acini (hematoxylin and eosin stain; reduced from a photomicrograph with a magnification of 480 diameters).

as 1.5 Gm. of pancreatic tissue, provided it is normal, seems scarcely sufficient to affect seriously the carbohydrate metabolism. Although in this case the number of well formed islands was not increased, we could observe a diffuse amount of islet cells between the acinous tissue. They were not very conspicuous or abundant and did not resemble islet adenomas. Their significance in the production of the clinical symptoms cannot be estimated. Fanta³ reported similar observations made on a man aged 37 who suffered from symptoms of hypoglycemia together with hyperchlorhydria. There was in his case a walnut size nodule of aberrant pancreatic tissue on the duodenum. The patient improved following removal of the aberrant tissue but still was subject to some symptoms of hypoglycemia. As remarked by Fanta, aberrant pancreatic tissue does not have the same significance as an islet adenoma. Nevertheless, any patient with hyperinsulinism who fails to exhibit an adenoma of the pancreas at surgical exploration should be carefully examined for the presence of aberrant pancreatic tissue.

SUMMARY

Surgical removal of aberrant pancreatic tissue from the wall of the duodenum produced relief of symptoms of hyperinsulinism.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

CRURICAST BANDAGE ACCEPTABLE

Manufacturer: E. K. Demmel Company, 59-11-67th Avenue, Ridgewood, Brooklyn.

Cruricast Bandages are gauze bandages impregnated with a zinc gelatin paste, prepared in the form of a moist roller bandage of a 10 yard standard length, wrapped in two sheets of waxed paper and packed individually or in dozen sealed containers.

The zinc paste used for the impregnation of the bandages has a low melting point and the formula is slightly varied for winter or for summer use to suit changes in climatic conditions. Made in 3 inch and 4 inch widths, the bandages have the white color of a zinc ointment. A dressing of gauze or stockinet should be applied over a cast made from a Cruricast Bandage to protect clothing.

Cruricast Bandages provide a compressive and supportive dressing which is soft and resilient. This dressing is porous to allow perspiration and evaporation and is of sufficient strength to prevent expansion from pressure of body heat. Data submitted by a reliable testing laboratory certifies to the strength of a three-ply cast made from a Cruricast Bandage.

Cruricast Bandage.

The average breaking load was warp 71.3 pounds and filling 42.3 pounds. The breaking load test was made by the "grab method." A sample was broken in the piece. Back jaws 2 inches wide, front jaws 1 inch wide, distance between jaws 1 inch, speed of pulling jaw 12 inches per minute. Capacity of machine 0-110 pounds. A sample was conditioned for four hours in

an atmosphere of 71 F. temperature and 65 per cent relative humidity before testing.

The bandages may be put directly on the skin or on ulcerated areas. The outer layers dry slowly; the layers next to the skin remain fairly moist, thereby retaining the medication in ointment form and prolonging the effect of the active ingredients. There is approximately 53 mg. of calcium chloride in each gram of bandage made up according to the summer formula and about 75 mg. of calcium chloride in each gram of bandage made up according to the winter formula. In the interest of national defense, the amount of zinc oxide in the formula has been reduced and kaolin has been substituted.

Cruricast Bandages will not dry as quickly as an Unna's boot prepared according to the National Formulary. Drying can be hastened by powdering with talcum or spraying with a solution of 1.5 per cent formaldehyde in water. A sprayer for this purpose is available. When formaldehyde is used, ulcerated areas and open wounds should be well covered to prevent contact with the solution.

The therapeutic action and effect of Cruricast Bandages are similar to those of an Unna's paste dressing. However, Cruricast Bandages do not require heating and their application is more simple for office use.

In the Council examination the Cruricast Bandages were used on ambulatory patients who attended the surgical clinic at a large hospital. The application of the bandages was found to be quite easy and they formed a soft elastic and flexible support. Compared with other bandages of this type on the market the Cruricast Bandage does not dry readily and, according to patients who have worn other types of zinc-gelatin bandages, they moisten the stockings more easily. It is for this purpose that a spray of 1.5 per cent formaldehyde is advocated, which complicates the procedure. Since the addition of kaolin the bandage has been somewhat drier.

The Council voted to accept the Cruricast Bandage for inclusion on its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

IN JUNE 1941 THERE APPEARED IN THE NEW YORK STATE JOURNAL OF MEDICINE A COMMUNICATION ON THE USE OF A PREPARATION KNOWN AS COLI METABOLIN IN THE TREATMENT OF HAY FEVER. THE CONTENTS OF THIS ARTICLE WERE REFERRED TO SO OPTIMISTICALLY IN TIME MAGAZINE AND A NEWS COLUMN ON HEALTH THAT MANY INQUIRIES FROM THE PUBLIC AND THE MEDICAL PROFESSION HAVE BEEN RECEIVED AT THE COUNCIL OFFICE. THESE INQUIRIES INDICATE THAT A WIDESPREAD IMPRESSION HAS BEEN CREATED THAT THIS AGENT MUST BE OF DECIDED VALUE TO HAVE RECEIVED SO MUCH PUBLICITY. WHILE COLI METABOLIN (TOSSE) HAS NOT BEEN PRESENTED FOR COUNCIL CONSIDERATION, IT WAS NEVERTHELESS DEEMED ESSENTIAL IN THE INTEREST OF RATIONAL THERAPEUTICS FOR THE COUNCIL TO PUBLISH THE FOLLOWING REPORT

AUSTIN E. SMITH, M.D., Acting Secretary.

COLI METABOLIN (TOSSE) NOT ACCEPTABLE FOR N. N. R.

A recent report¹ in the *New York State Journal of Medicine* presented an optimistic picture for hay fever sufferers by implying that an agent known as Coli Metabolin had been found to effect cures in a high percentage of cases. Shortly after this article appeared, its context was reproduced in *Time* magazine² and in a news column on health by Dr. Logan Clendenning with the inviting captions "Last Sniffle?" and "New Hay Fever Remedy Tested Successfully." Immediately members of the medical profession began to receive inquiries from the public. Obviously the publicity afforded through the press had not passed unnoticed.

The author of the paper which appeared in the *New York State Journal of Medicine* was Dr. Ernest J. Elsbach, a physician who received his medical training, according to available records, in Europe and who was granted a license in 1938 to practice medicine in New York State. According to Dr. Elsbach, Coli Metabolin (Tosse) has been successfully used in the treatment of "hay fever," "allergic asthma" and "allergic eczema." The Elsbach paper is short, consisting of only about one and a half pages; yet half of this brief report is devoted to a general discussion of allergic rhinitis. The remainder of the paper contains what is presumed to be a description of the agent and the results following its use; but the latter aspect received little detailed attention, considering the optimistic tone of the article. Noticeably absent is any mention of the use of controls or statistical analysis. The number of patients treated was 75, but no details can be found in this paper on any untoward reactions or on the criteria on which the claim of a "cure" was based.

The following statements regarding Coli Metabolin appear in an advertising circular issued by the Tosse Laboratories:

"... a new biological treatment ... which appears to act to a high degree as a stimulant to the natural functions of the sympathetic system. It consists of the metabolin of the coli bacteria, grown on specific culture media. The action of this natural metabolic product is by no means a non-specific protoplasm activation, because its effect is the same, even when the preparation is de-proteinized by heating. Its action on the sympathetic nervous system seems to be very pronounced and have a desensitizing effect. The best causal therapy is, of course, that of giving the appropriate remedy, after an exact diagnosis has been made, or of approaching the nervous system itself and bringing it into such a condition that it no longer reacts to any irritant. Many investigations and experiments have disclosed that in every infectious disorder of the body, the curative effect is exerted through influence of the nervous system or the endothelial system. The principal remedies, intended to stimulate the system to resist infection, are autohemotherapy, protein bodies of various kinds and other albuminous substances."

These statements, together with others of a similar indefinite speculative tenor, may serve to impress the more susceptible reader but will not be regarded by critical investigators as offering much information on the exact nature of the preparation or its specific mode of action. Final instructions in the circular read "During treatment, the patient should not

1. Elsbach, Ernest J.: A New Treatment for Hay Fever, *New York State J. Med.* 41: 1248 (June 15) 1941.
2. Last Sniffle? *Time*, June 30, 1941, p. 48.

change his place of residence, and, while no special diet is required, raw strawberries should be avoided. Abstinence from alcohol is essential."

Even the most casual reader will not fail to notice a similarity between certain statements appearing in the Elsbach article and in the advertising circular. In fact, direct quotations may be noted in several instances. Neither source, however, suggests what the exact ingredients of Coli Metabolin may be, except to refer to them as "metabolins." According to definitions in current dictionaries, metabolin can be considered as a rather broad term to designate any product of metabolism. It is obviously a term with "elastic possibilities."

Of the letters arriving at the Council office, not all have been inquiries, some have been complaints. One physician wrote to tell of a telephone call from a woman suffering from chronic asthma who wrote to Dr. Elsbach to inquire about the treatment; the letter received in the Council office states that this woman was informed that "it would be necessary for her to come to New York and his charge for testing and administering this product would be \$220 (cash)." Another physician, not a resident of New York State, wrote saying he was informed that the cost of purchasing the material (presumably a package containing 12 ampuls of 2 cc each) was \$22. A third physician, a resident of Chicago, inquired of Dr. Elsbach as to the cost of treatments and the possibility of success; Dr. Elsbach replied "I am absolutely not inclined to promise anything."

A number of physicians have forwarded to the Council office copies of the advertising circular. One physician in Chicago mailed a specimen of the package container with 2 ampuls of Coli Metabolin and a package insert. Imprinted on the glass ampuls is E. Tosse & Co., Inc., 2 cc Plus, Coli Metabolin For Intramuscular Injection. Made in U. S. A. Control 15C81.

The insert advocates the use of Coli Metabolin (Tosse) in the treatment of "hay-fever and allergic asthma" and states that the product is "a solution of the products of the metabolic processes of E. coli. Their metabolism is influenced and controlled by the enrichment of their culture medium by the use of ascitic fluid and sugars and by the differential procedures in their culture. The final product is a solution of the filtrable and soluble solution. The final product is a sterile mobile liquid, containing no coli organisms." Under a section entitled Indications and Administration there appears the statement "Although no definite statement can at present be made as to the etiology of vasomotor rhinitis and related allergic manifestations, the use of Coli Metabolin Tosse is predicated upon the belief that allergic manifestations may be neurogenic entities, intimately bound up with the physiology of the sympathetic nervous system."

Stamped on the circulars and inserts is the statement to the effect that Coli Metabolin is available in New York State only, as it is not sold in interstate commerce. It is the understanding of the Council that in May 1937 E. Tosse and Company, Inc., informed the Division of Biologics Control National Institute of Health, that it had "acquired the manufacturing rights for the preparation of 'Antigens of Coli Bacteria'" and inquired with respect to the requirements for a license for the product and in 1941 submitted formal application for license. License has not been granted because the firm "failed to present evidence of the therapeutic or prophylactic value of the product."

While E. Tosse and Company confines its claims for Coli Metabolin to its use in allergic conditions it is interesting to note that in 1938 a German firm, Leimwerk Dr. Ernst Laves, Hanover, Germany, applied for a license for "Coli Antigen Laves." The latter firm was not granted a license either. The following summary of the claims made by the German concern has been supplied to the Council office:

Reduction of 'red blood pressure but not 'white blood pressure, reduction of the rigidity in multiple sclerosis, relief of spasm in spastic constipation, spastic gall bladder affections, singultus, meteorism, essential hemorrhoidal disorders included under the term "Hepato-vegetopathy", angina pectoris, hay fever, regulates the vegetative nervous system, a reciprocal action with the glands of internal secretion, bronchial asthma, vasomotor cardiac weakness, spastic gall bladder disorder."

A third product, known as Mutaflor, is also prepared from B. coli. A summary of the claims which are made in a circular prepared by the firm Hageda A. G., Berlin, was supplied to the Council office at the same time as the summary of the claims for Coli-Antigen Laves. The conditions for which Mutaflor was advocated are:

"(1) Chronic catarrh of a large intestine (colitis), (2) Digestive disturbances with abnormal putrefaction or fermentation processes (dyspepsia), (3) Ulcers of stomach and duodenum, (4) Chronic constipation (atonic and spastic), (5) Constant carriers of infectious germs, (6) Acute and chronic dysentery, (7) Diseases caused by intestinal poisons, localized in other organs (a) cutaneous eruptions including urticaria and crusts, lactaria (b) chronic diseases of the joints, (c) ischias, (d) pernicious anemia (e) inflammation of kidney pelvis and bladder, (f) many cases of disturbances during menstruation and menopause (g) migraine, (h) high blood pressure (i) many cases of sleeplessness and heightened mental fatigue. Furthermore, Mutaflor may be of assistance without direct effect on the main disease in cardiac trouble with intestinal flatulence (stopping of attacks), and in the 'toxic intestinal catarrhs of lung tuberculosis etc."

These are indeed impressive claims for an article the exact nature and mode of action of which appears so vague.

No product of E. Tosse and Co., Inc. stands accepted by the Council for inclusion in New and Nonofficial Remedies. Recent advertising indicates that the firm markets a number of preparations bearing such noninformative names as Arso-plasma, Bismogenol, Ekzebro, Kavalactol, Nitroscleran and Strophalen. Advertising material in the Council office reveals that in 1931 Bismogenol was a suspension of bismuth salicylate in oil for "the treatment of syphilis in all stages", Nitroscleran was "sodium nitrate combined with inorganic (Trunezek) serum" for the "treatment of hypertension, incipient arteriosclerosis, coronary sclerosis, angina pectoris, intermittent claudication", and Ekzebro was a "combination of bromine and strontium in an isotonic sodium chloride solution" for the "treatment of all forms of eczema, urticaria, psoriasis, toxic erythema and all itching dermatoses, also nervous disorders, allergy, sympathicotonia, neurasthenia."

The Council office directed a letter to the firm asking for information on Coli Metabolin so inquiring physicians might receive as much information as was available. The letter was referred to Dr. Cavan and Brown, consulting chemists in Brooklyn whose reply contained little information that could not be gathered from the advertising material for Coli Metabolin except for the pertinent statement "We have advised the firm of the advantages of submitting the product to the Council, and have been told that inasmuch as it is in the process of a patent application, they cannot do so at the present time and not invalidate their patent rights through disclosure."

In considering a product for inclusion in New and Nonofficial Remedies, the Council requires a fully informative statement of composition so that the physician may know what he is prescribing. The Council also insists that the claims of manufacturers or agents concerning the therapeutic properties of their products must be compatible with demonstrable facts. For clinical evidence to be acceptable, it must offer sufficient objective data to enable the Council to confirm the facts and establish the scientific value of the conclusions drawn. The acceptance of evidence is determined mainly by its quality, and the evidence furnished must be in sufficient detail to permit judgment as to the care with which it was gathered and the validity of the deductions.

Obviously, present evidence indicates that Coli Metabolin (Tosse) is incompatible with the rules of the Council. Its composition may be said to be indefinite. Although the firm claims that the preparation has the same effect even when it is "deproteinized by heating," no indisputable evidence appears in its literature to support this statement.

The Council voted to declare Coli Metabolin (Tosse) unacceptable for inclusion in New and Nonofficial Remedies because (1) its composition is indefinite and semisecret, (2) the claims made are not supported by valid scientific evidence known to the Council or generally available.

CLIMACTERIC IN AGING MEN

Recently many reports have appeared in medical journals claiming that a climacteric occurs in middle aged men.¹ Brochures circulated by pharmaceutical manufacturers depict the woful course of aging man. None too subtly these brochures recommend that male hormone substance, like a veritable elixir of youth, may prevent or compensate for the otherwise inevitable decline. What of the postulated occurrence of a climacteric in men? The facts allow a reasonable analysis.

Female mammals below primates do not pass through a menopause, since they do not menstruate. A thorough study has not been made of subhuman primates. In old female rodents the reproductive status is unlike that in elderly women, for the decline of ovarian function is gradual and a return of reproductive function can be induced on stimulation by exogenous gonadotropic substances.² Indeed in aged mice and rats, as contrasted with women after the menopause, the ovaries contain ova after reproductive cycles disappear, and the degree of ovarian atrophy is much less severe.³ This dissimilarity between the rodent and the primate recalls a similar difference in the amount of retrogressive changes in the testes after hypophysectomy or cryptorchism, the primate (monkey) showing a much less degree of spermatogenesis than the rat.⁴

Available data allow examination of the essential nature of the menopause only as it occurs in women.

4 Smith, P. E. Comparative Effects of Hypophysectomy and Therapy on the Testes of Monkeys and Rats, in Les hormones sexuelles, edited by L. Pincus 3:271, 1938.

The primary phenomenon is ovarian failure, the ovary becoming atrophic and containing only a reduced number of ova.⁵ In late years ova disappear entirely. Decreased ovarian function, whether in the menopause or after bilateral ovariectomy, is followed by diminished secretion of estrogens and by an increase in the quantity of gonadotropins as measured in the urine.⁶ Elevated titers of urinary gonadotropins are observed continuously into old age⁷ and apparently are the result of hypersecretion by the pituitary.

Although the injection of exogenous gonadotropins has been claimed to reactivate the ovaries,⁸ this has been denied.³ Probably the ovaries of older women are at least less responsive than those of younger women.⁹ This insensitivity to gonadotropins observed in older women recalls a similar phenomenon in immature animals.¹⁰

Vascular and psychoneurologic complications are common, the former occurring in two thirds of menopausal women.¹¹ Other complications that occur frequently are headache, giddiness and "rheumatic" pains.¹¹ The nature of vascular phenomena at the menopause has been examined recently by Reynolds and his co-workers¹² and by Scherf.¹³

If men pass through a comparable climacteric state there should be evident (1) testicular insufficiency with (2) a pronounced compensatory hyperexcretion of gonadotropins and (3) the occurrence of vasomotor and other phenomena similar to those seen in menopausal women. However, evidence of an abrupt, spontaneously occurring climacteric in normal men has not been produced. The data accumulating from many reports have not indicated an abrupt decrease in the excretion of urinary androgens by normal men prior to senility, even though somewhat smaller quantities are excreted in the later years.¹⁴ Dingemans, Bor-

chardt and Laquer¹⁵ report an average excretion per liter of 19 international units in men 59 to 67 years of age in contrast with the 40 to 50 international units per liter in men 20 to 34 years of age. Fraser and his co-workers¹⁶ found values with colorimetric assay to be 1.8 to 4.8 mg. in men 71 to 75 years of age, a sharp contrast to the average of 13.8 mg. in young male adults. Dingemans and her collaborators report, however, the excretion of 35 and 50 international units by two men 80 years of age, which emphasizes the point that no sudden gonadal dysfunction comparable to that in women is known to occur at any set age range.

The continued excretion of androgens cannot be explained by substitution of secretions from the adrenal or other sources, for on removal of the testes the quantities of urinary androgen rapidly diminish.¹⁷

Neither is there known to be any sudden or material elevation in the quantities of urinary gonadotropins excreted by aging men such as in women after the menopause.¹⁸ This fact is relevant to an understanding of testicular secretion in older men. Although hypersecretion of gonadotropins occurs in actual instances of primary testicular insufficiency, the excretion of urinary gonadotropins apparently does not rise in aging men as might be expected as a result of claimed decrease in testicular secretion. The inference might be drawn that the production of gonadotropins by the pituitary becomes less in some men during later years. If so, the reduced testicular function would be secondary.

The occurrence of vasomotor phenomena comparable to those in menopausal women are apparently infrequent despite claims that men in the fourth and fifth decades exhibit such vascular changes along with a number of specific and nonspecific complaints.¹⁹

Primary testicular insufficiency results in a climacteric-like state. In men, as in women, a "climacteric

state" obtains when there is a primary gonadal insufficiency with decrease in gonadal secretions and increase in the quantities of urinary gonadotropins.²⁰ The titers of urinary gonadotropins are comparable to those in menopausal women and, in some castrate men, are in the higher portion of the range found in ovariectomized women.²¹ Two of three men castrated prepuberally and now in their sixth decade have been observed each to excrete 160 mouse units.²² Apparently hyperproduction of gonadotropins has continued for the almost half century these men have lived since castration. A climacteric state does not occur, however, either in women²³ or in men²² when the gonadal insufficiency is secondary to hypofunction of the pituitary.

In the castrate man vasomotor phenomena are severe in many instances and appear with the intensity seen in ovariectomized women. In some castrates palpitation, dyspnea on effort and other phenomena observed in certain menopausal women occur.¹³ Charts show the frequency of hot flushes and sweating in a castrate man and their temporary control during treatment with testosterone propionate. This significance of psychogenic factors is suggested by the lessened effectiveness of endocrine therapy during periods when the patients are especially apprehensive and disturbed.

Although the prerequisite for a climacteric-like state in men, namely a primary testicular insufficiency with evidence of a compensatory hypersecretion of gonadotropins, is seldom fulfilled spontaneously, a few instances might be observed, such perhaps as those reported by Heller and his associates²⁴ as "involutional" cases (age not stated) in which large quantities of urinary gonadotropins were excreted. Possibly bilaterally cryptorchid men might exhibit climacteric-like phenomena, for experimentation in several species of animals shows that long-continued cryptorchism results in the secretion of subnormal amounts of male hormone substance. Hess, Kunstadter and Saphir²⁵ have stated that urinary gonadotropins are present in supranormal quantities in bilaterally cryptorchid boys.

Cases of primary testicular insufficiency are observed only infrequently as in severe orchitis, traumatic castration and surgical castration, as for medicolegal purposes or incidental to management of such matters as hernias, hydroceles and tumors.

Androgens exert a tonic and stimulating action, associated perhaps with their metabolic effects.²⁶ Male hormones provide replacement therapy in castrates but are active also in normal middle aged men beset by aging processes which are in some large proportion irrespective of testicular function. Androgens may influence quite harmfully the physiologic and psychologic condition of previously well adjusted elderly men, as has been observed incidental to the trial use of male hormone substances in the treatment of benign hypertrophy of the prostate. Actual evaluation of androgenic treatment cannot be avoided by glib explanation that men normally undergo a spontaneous climacteric, an abruptly occurring state of primary testicular insufficiency in which male hormones act as substitutional therapy. Primary gonadal insufficiency in men induces "climacteric phenomena" quite comparable to those in menopausal women. In normal men, however, a sudden, spontaneous onset of primary testicular insufficiency is observed only infrequently, lacking any evidence of rapid decrease in the production of gonadal hormones and compensatory increase in urinary gonadotropic substances, such as are characteristic of the menopause.

EPIDEMIC VIRUS CONJUNCTIVITIS

During the summer of 1941, according to Holmes,¹ a rapidly spreading type of acute conjunctivitis raged in Oahu, Hawaii. At first, patients and doctors called it "pink eye." However, when repeated cultures and smears were made from conjunctival scrapings and secretions from more than 50 cases, investigators found it impossible to determine any offending organism. In October a considerable number of cases began to appear in California, and the peak of the outbreak was reached in December. At that time authorities noted that 2 per cent of workers in some ship building plants were affected, but the percentage of those affected was higher in special groups, such as welders, whose eyes are notoriously subjected to the trauma of light.

After an incubation period of from two to five days the patients experience pain, excessive lacrimation and the feeling that some granular dusty body or some other foreign substance is in the eye. There is extensive edema, but a purulent discharge is seldom seen. The upper lids are usually reddened and swollen, and blepharospasm is encountered. In many instances ophthalmologists report that the palpebral conjunctivas are intensely reddened, edematous and congested; some have noted also that the bulbar conjunctivas are similarly affected. In Hawaii a characteristic and almost

pathognomonic observation was the appearance of multiple subconjunctival hemorrhages on the tarsal portions of the conjunctivas.

In most instances the disease seemed to be self limited. It pursues a leisurely clinical course, in the absence of complications, lasting from two to three weeks. When corneal infiltrates developed, the eyes remained irritated for from four to six weeks or longer. Among the complications were infiltrates of the cornea, which appeared as grayish dots. With the aid of the slit lamp, minute deposits were seen forming a faint haze on the basal layers of the corneal epithelium. In some instances, when secondary infections occurred there was hemorrhagic conjunctivitis, and in a few cases there were ulcers of the cornea.

Thus far attempts to determine the cause of this conjunctivitis have been unavailing, but practically all the observers believe that a specific virus is responsible. In California the health department reports that inoculation of the scrapings into mice, guinea pigs, rabbits and monkeys gave negative results. Also attempts to make aerobic and anaerobic cultures yielded nothing. Studies are being continued in several laboratories with a view to isolating a virus or developing more information concerning the nature of the infection.

As is usual, the person who became infected was inclined to claim as the cause the last activity in which he engaged. The worker at an emery wheel was certain that a piece of the wheel struck his eye, the worker in the pineapple canneries stated that pineapple juice in the eye was responsible, swimmers said that the infection was due to swimming in contaminated water, and welders felt that the disease was directly due to the welding process.

The prevention of this, as of other infections concerning the eye, is definitely related to the prevention of contamination by soiled hands and linens. In industrial plants, medical control of the industrial worker is necessary.

The condition as it occurred in California seemed to be much less virulent and to have a lower grade transmission rate than that in Hawaii. Thus far all methods of specific treatment have been unavailing. Physicians in Hawaii and in California tried the mild silver preparations, various arsenic preparations, zinc, silver nitrate and alum with the observation that some of these methods of treatment seemed to aggravate the condition rather than to produce benefit. Most comforting was the application of cold compresses. Incidentally, the application of infra-red and other rays, both generally and locally, and the use of sulfonamide derivatives were also unavailing. The complications affecting the eye were treated by the usual technic of dilation and the use of iodine preparations for hastening the absorption of corneal infiltrates.

Current Comment

NEW INSECT VECTORS FOR BUBONIC PLAGUE

Isolation of virulent plague bacilli from avian fleas has been reported by Wheeler, Douglas and Evans¹ of the Hooper Foundation, San Francisco. Thirty years ago Rucker² suggested that predatory birds may play a role in the spread of bubonic plague. The suggestion, however, was not supported by experimental evidence. Within the last few years, confirmatory evidence has been reported by Jellison,³ who demonstrated that rodent fleas are frequently transported by predatory birds to their nests on freshly killed rodents. From none of the transported fleas, however, was he able to recover the plague bacillus. An opportunity to test the Rucker theory was afforded by a recent local outbreak of plague among the ground squirrels in central California. Two months after the peak of the epizootic a burrowing owl was captured about 5 miles outside the infected area. This owl was the carrier of numerous "sticktight" fleas, an avian species (*Echidnophaga gallinacea*), found abundantly on hawks, owls, chickens and other domestic fowls and often present on rodents and coyotes. A mass inoculation of these avian fleas into a guinea pig proved that they were the carriers of virulent plague bacilli. This is apparently the first definite proof of avian transmission of plague infected insects. As far as known the birds themselves are not susceptible to the plague bacillus. The association of burrowing owls with colonies of ground squirrels, however, is epidemiologically interesting.

PREMATURE ENTHUSIASM ABOUT COLI METABOLIN (TOSSE)

Elsewhere in *THE JOURNAL*⁴ appears a report by the Council on Pharmacy and Chemistry on a preparation known as Coli Metabolin (Tosse), which is advocated for the treatment of hay fever and allergic asthma. This preparation has been the subject of numerous inquiries received at the headquarters of the American Medical Association. The majority of the inquiries appear to have arisen as a result of articles in lay publications based on a short communication by Dr. Ernest J. Elsbach published in the *New York State Journal of Medicine*. From the Council report it may be inferred that critical investigators will consider the Elsbach article premature and unscientific, since little evidence is presented to justify the enthusiastic attitude of the author. According to the Council, the composition and exact mode of action of Coli Metabolin (Tosse) are indefinite and the claims of the firm are not supported by available valid scientific evidence. Thus, Coli Metabolin (Tosse) has been declared unacceptable for inclusion in New and Nonofficial Remedies. In order to be eligible for interstate commerce, biologic

products and certain other therapeutic agents such as the arsphenamines must be licensed following consideration by the Division of Biologics Control of the National Institute of Health of the U. S. Public Health Service. The latter agency had refused to grant a license to the Tosse Laboratories permitting shipment of Coli Metabolin in interstate commerce. Nevertheless the product received some distribution, presumably under the pretext that it was intended for "investigational use only." It is entirely proper that laws regulating the movement of drugs in interstate commerce should provide exceptions for articles intended for legitimate research. Nevertheless, such exceptions are obviously open to serious abuse. The federal authorities have the particularly grave responsibility of making certain that the public is protected from those who choose this loophole as an outlet for drugs that have not established that right to a place on the American market. Any one with knowledge of the commercial distribution of such drugs will do well to inform the proper legal authorities.

THE PIGMENT OF THE MALARIA PARASITE

As the malaria parasite develops inside the red blood cells, the hemoglobin content of the cells diminishes and a dark colored pigment accumulates within the cells. Carbone,¹ Ascoli² and Brown³ identified this pigment spectroscopically as hematin. However, their methods of extraction did not preclude the possibility that the hematin had been liberated from some preexisting complex. Fairley and Bromfield⁴ described a pigment in the plasma of a patient with blackwater fever which spectroscopically appeared similar to methemoglobin. Further study of the pigment, however, suggested that it was a compound of hematin and plasma albumin to which Fairley gave the name "methemalbumin." In view of this diverse opinion a reinvestigation of the chemical identity of the malaria pigment was undertaken by Morrison and Anderson,⁵ who obtained their parasite material from the blood of monkeys infected with *Plasmodium knowlesi*. In some animals these authors found as much as 75 per cent of the total erythrocytes containing malaria parasites in terminal infection. They dissolved the pigment from the parasite mass with sodium carbonate solution and then demonstrated the identity of its spectrophotometric curve with that of a solution of recrystallized hemin in 0.5 normal sodium carbonate. Morrison and Anderson thus confirmed the observation by Sinton and Ghosh⁶ that 0.5 normal sodium carbonate does not alter hemoglobin within the time required to dissolve the pigment from the parasite. The pigment itself, they proved, is identifiable spectrophotometrically as hematin (ferrihemic acid). The study is being continued to determine, if possible, the role of the pigment in the malaria syndrome.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT OF OFFICERS FOR MEDICAL DEPARTMENT, ARMY OF THE UNITED STATES

The following memorandum was sent by the Adjutant General's Office to all corps area and department commanders on January 21:

1. Letter from this office dated Feb. 3, 1941, file AG 381 (8-13-40) R-A, Subject: "Assistance of the American Medical Association in the classification and procurement of physicians for the military service," is rescinded.

2. There has been established under the Office for Emergency Management, Office of Defense Health and Welfare Services, a Procurement and Assignment Service to coordinate the procurement of physicians, dentists and veterinarians for all governmental, industrial and civilian requirements.

3. In order to expedite appointments in the Medical Corps, Dental Corps and Veterinary Corps, Army of the United States, the following procedure will govern the processing of all applications:

(a) All individual inquiries for information concerning a commission or offers to serve as a medical, dental or veterinary officer should be acknowledged by the headquarters receiving the communication and the communication itself forwarded by indorsement to the Executive Officer, Procurement and Assignment Service, Office of Defense Health and Welfare Services, Social Security Building, Washington, D. C.

(b) The Procurement and Assignment Service will supply to individual applicants who are eligible and qualified for appointment, the required forms (WD AGO Form No. 170, "Application for Appointment and Statement of Preferences for Reserve Officers," in duplicate, and WD AGO Form No. 178 and 178-2, both in duplicate) together with a request on the surgeon of the nearest army post for a final type physical examination. Each request for final type physical examination authorized by the Procurement and Assignment Service will be honored by surgeons of army posts. Application forms and supporting papers, except the report of physical examination, will be returned by the applicant to the Procurement and Assignment Service; the report of physical examination (WD AGO Form No. 63), will be forwarded by the surgeon of the

station at which the examination was conducted, direct to the Surgeon General.

(c) The completed applications and supporting papers, except report of physical examination, will be transmitted by the Procurement and Assignment Service to the Surgeon General together with a statement by that service derived from its files and regarding eligibility of the applicant for appointment in the Medical, Dental and Veterinary Corps, Army of the United States, as prescribed by current Army Regulations. The Procurement and Assignment Service will also furnish the Surgeon General with the professional classification and evaluation of the applicant as determined from the recent nationwide survey made by the Committee on Medical Preparedness of the American Medical Association.

(d) The Surgeon General will forward such completed applications to the Adjutant General as prescribed in paragraph 10 (4), Army Regulations No. 605-10, and inform the Procurement and Assignment Service of the action recommended.

4. No change in the present procedure for the appointment of graduates of medical units of the Reserve Officers' Training Corps in the Medical Corps Reserve; nor for appointment in the Army of the United States of physicians and dentists for affiliated units; of junior and senior students in medical schools in the Medical Administrative Corps, Army of the United States; nor of graduates of such schools who are to be appointed in the Medical Corps, Army of the United States, on graduation.

5. When the applications for appointment have been approved, the Adjutant General will notify the applicant direct of his appointment with instructions as to proper completion of oath of office and finger print card and the return of such forms direct to the Adjutant General. When the oath of office has been received by the Adjutant General, the Surgeon General and the Executive Officer, Procurement and Assignment Service of the Office of Defense Health and Welfare Services, Office for Emergency Management, Washington, D. C., will be notified.

By order of the Secretary of War.

OCCUPATIONAL DEFERMENTS OF PHYSICIANS, DENTISTS AND DOCTORS OF VETERINARY MEDICINE

The following memorandum was released to all state directors of the Selective Service System on January 28:

Information previously distributed by this headquarters clearly indicates an overall shortage of physicians, dentists and doctors of veterinary medicine in the nation. Since war was declared, the shortage of these professional men has become acute. It is now manifest that every qualified doctor, dentist and veterinarian must serve where he can render the greatest professional service to the nation.

In order to accomplish this purpose, the President, by executive order, has formed the Procurement and Assignment Service, under the Office of Defense Health and Welfare Services. This service was formed primarily for the purpose of gathering

and making available information with respect to the supply of qualified practitioners in the fields of medicine, dentistry and veterinary medicine, with a view of securing the most effective allocation of medical manpower as indicated by the requirements of the armed forces, civilian needs and industrial medicine.

To work with the headquarters of this service in Washington, there is being organized a committee for each corps area in the continental United States. Each committee will consist of five doctors, two dentists and one veterinarian. The committees have been accepted as advisers to the nine corps area surgeons, to the naval district surgeons and to the regional medical officers of the Office of Civilian Defense and will operate not only through the subdivisions of the medical, dental and veterinary

associations but also with the profession at large in securing information and giving advice.

When considering the classification of any registrant who is a qualified physician, dentist or doctor of veterinary medicine, the director of Selective Service desires that local boards, through the state director, shall consult the procurement and assignment committee of the corps area for information as to the availability of qualified physicians, dentists and doctors of veterinary medicine in the community. This information shall be considered by the local board in determining the registrant's classification. The executive order referred to in no way affects the authority of the Selective Service System to classify registrants. The procedure has been established for the purpose of making such information available to local boards.

THE ARMY CENTRAL EPIDEMIC CONTROL BOARD

As announced by the Secretary of War in January 1941, a Central Epidemic Control Board, composed of physicians from civil life, has been established to function as an adviser to the Surgeon General of the Army, Major General James C. Magee. Since establishment of this Central Control Board rates for respiratory disease in the Army have been unusually low, although measles and influenza, particularly measles, this winter are registering an incidence among the civil population in certain areas greater than the five year average for the country. The low rate is due in part to the fact that the troops are seasoned and thus better able to resist disease. The seven members of the Central Control Board are Dr. Francis G. Blake, president of the board, professor of medicine and dean of the Yale University School of Medicine; Dr. O. H. Perry Pepper, professor of medicine, University of Pennsylvania School of Medicine; Dr. Alphonse R. Dochez, professor of medicine, Columbia University College of Physicians and Surgeons; Dr. Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine; Dr. Kenneth F. Maxcy, professor of epidemiology, School of Hygiene and Public Health, Johns Hopkins University; Dr. Andrew J. Warren, assistant director, International Health Division, Rockefeller Foundation, and Dr. Oswald T. Avery, member of the Rockefeller Institute for Medical Research.

The consultants appointed to advise this Central Board are Dr. Wilbur Sawyer, director of the International Division, Rockefeller Foundation, and Dr. E. S. Robinson, director of the Division of Biological Laboratories of the Massachusetts Department of Health.

Operating under the Central Control Board are eight investigating commissions, each of which has a number of consultants and teams.

Heading the Commission on Influenza is Dr. Thomas Francis Jr., professor and chairman of the Department of Epidemiology of the School of Public Health, University of Michigan. This group is carrying on intensive studies on influenza vaccines in cooperation with the Rockefeller Foundation. It is also making a study of the efficiency of various types of respiratory masks and laboratory studies of specimens collected in the field bearing on the cause of, transmission of and bodily resistance to influenza and its complications. The group is also investigating possible methods of inducing immunity other than by vaccination. The influenza commission is organized into three teams: an eastern team with headquarters in New York, a midwestern team with headquarters at the University of Michigan and a far western team with headquarters in the California State Department of Health, Berkeley, Calif. Should there be an influenza epidemic, the commission will undertake research looking to the nature of the virus involved and will study the effectiveness of the sulfonamide derivatives in the prevention of complications due to bacteriologic invasion following reduction of bodily resistance by the virus.

The Commission on Pneumonia is headed by Dr. Colin M. MacLeod, professor of bacteriology in the New York University College of Medicine. This commission deals with every type of pneumonia and is carrying on studies dealing with the classification of the pneumonia organism. Experiments are

For the convenience of the state director and the local boards, the names and addresses of the chairmen of the nine corps area committees of the Procurement and Assignment Service are listed:

First Corps Area—Dr. W. G. Phippen, Salem, Mass.
Second Corps Area—Dr. A. W. Booth, Elmira, N. Y.
Third Corps Area—Dr. A. M. Shipley, Baltimore.
Fourth Corps Area—Dr. Edgar Greene, Atlanta, Ga.
Fifth Corps Area—Dr. E. L. Henderson, Louisville, Ky.
Sixth Corps Area—Dr. Charles H. Phifer, Chicago.
Seventh Corps Area—Dr. Roy W. Fouts, Omaha.
Eighth Corps Area—Dr. Sam E. Thompson, Kerrville, Texas.
Ninth Corps Area—Dr. Charles A. Dukes, Oakland, Calif.

LEWIS B. HERSHEY, Director.

being conducted in methods of immunization employing civilian volunteers and in the use of chemical agents in the management of empyema. In event of epidemics of pneumonia in the Army, this commission will conduct examinations in the field to determine the nature of the infecting agent and to make such other studies as may be necessary for the development of effective control measures. Such field investigations may be made independently or in collaboration with the commissions on influenza, measles and hemolytic streptococcus infections. Following a preliminary inquiry of cases of atypical pneumonia at an army camp, a team composed of Dr. John H. Dingle of Harvard University, Dr. Berry Wood of Johns Hopkins University and Dr. Gerritt J. Budding of Vanderbilt University was sent to make a study of this disease.

The Commission on Hemolytic Streptococcus Diseases is headed by Dr. Martin H. Dawson of the Columbia University College of Physicians and Surgeons. This group arranges also for the manufacture and purchase of diagnostic streptococcus typing serums and the establishment of central group and typing laboratories and assists in collaboration with other commissions and with the Army Medical School in the grouping and typing of streptococcus strains. Attention is being given to the determination of the effect of the sulfonamide derivatives in the carrier state of the hemolytic streptococcus. The commission is now undertaking a special field investigation in the fifth and sixth corps areas in order to complete a preepidemic survey of the types of infectious organisms present and their relationship to scarlet fever and acute rheumatic fever. This work is being directed by Dr. Francis F. Schwenker of the International Health Division of the Rockefeller Foundation.

Dr. Joseph Stokes Jr., professor of pediatrics at the University of Pennsylvania School of Medicine, heads the Commission on Measles, which deals with tests to detect the susceptibility to infection of individuals and undertakes to determine the possibility of inducing active immunity by the use of certain protein fractions of the blood. The group has also been charged with the additional duty of undertaking pertinent studies in mumps, with special emphasis on means of reducing the incidence of orchitis. Field investigation deals particularly with the effect of sulfonamide derivatives on the incidence and control of the bacteriologic complications of measles.

Dr. Perrin H. Long, professor of preventive medicine of the Johns Hopkins University School of Medicine, Baltimore, heads the Commission on Meningococcic Meningitis. This commission has established a central laboratory at the Johns Hopkins University to receive and type strains of meningococci, to standardize typing serums and to maintain and analyze therapeutic records on meningococcic meningitis in the Army. The commission is conducting studies dealing with the classification of the disease producing agent, the various serums used for diagnostic purposes and the curative effect of the sulfonamide derivatives. In event of a threatened epidemic of meningococcic meningitis in the Army, this commission will be called on to aid in developing control measures, to conduct bacteriologic investigation concerning the prevalence of types of meningococci and to study the epidemic aspects of the outbreaks and the effects of chemotherapeutic agents on the incidence and duration of the carrier state.

Dr John R Paul, associate professor of medicine of the Yale University School of Medicine heads the Commission on Neurotropic Virus Diseases New fields for research have been opened up with the development of new laboratory procedures for the diagnosis and differentiation of neurotropic virus disease and a special virus laboratory was set up at the Army Medical School in October 1941 This laboratory is collaborating with the commission in serologic and immunologic studies The chief object of field studies to be undertaken will be the development of control measures and search for the presence of the virus in materials from patients Particular attention is being given to the possible relationship by the sleeping sickness of horses and that of man A vaccine which affords protection to horses leads to the hope that similar protection may be conferred on man—an important question which will be investigated

Dr Stanhope Bayne-Jones, professor of bacteriology at the Yale University School of Medicine, heads the Commission on Epidemiological Survey The duty of this commission is essentially that of counterespionage—a detector command which will keep constant check on organisms producing disease in man This commission conducts periodic surveys throughout the year in different geographic areas of the country to determine the presence of disease germs in the upper respiratory tract of selected groups of soldiers The purpose of these surveys is to furnish a base line of the “normal” incidence of respiratory pathogens and to watch for significant changes in respiratory flora which might indicate the imminence of epidemics of respiratory diseases Such a study of military personnel in camps in the first corps area is now being made by a team composed of Dr J Howard Mueller, Dr John F Enders and Dr George Hartley Jr, all of Harvard University Another investigation of “San Joaquin Valley fever” in personnel stationed at certain aviation training centers in California, is being carried on by the commission under the supervision of Dr Charles E Smith of Stanford University

Dr Oswald H Robertson of the Department of Medicine, University of Chicago Medical School, heads the Commission on Cross Infections in Hospitals This commission conducts long term studies on methods for reducing the existence of cross infection in hospital wards with special emphasis on the ultraviolet radiation and the development of effective chemical agents for the sterilization of air

DEFERMENTS OF PROFESSIONAL STUDENTS AND INSTRUCTORS

The Selective Service System, Washington, D C, on January 12, issued the following supplement to Memoranda (I 62), (I 91) (I-99) and (I-150) Occupational Deferment of Engineering, Chemical, Physics, Medical, Dental Students and Instructors (III)

The attention of local boards is again invited to the necessity of seriously considering for deferment students in certain specialized professional fields in which dangerously low levels of manpower are found to exist This memorandum is in addition to and does not rescind those previously issued which apply to students in other critical fields

Subsequent to the declaration of war, local Selective Service agencies have in many instances proceeded to classify registrants without regard to the fact that they are in training or preparation for activities the maintenance of which is essential to the national health safety or interest and war production This is particularly true in cases of engineering, chemical, physics, medical and dental students

Admittedly there is an overlapping of the military and civilian requirements of a nation at war, however, it must be borne in mind that the one is dependent on the other It is estimated that the expanding army will eventually require doctors and dentists in numbers heretofore unknown They will not be available if those students who show reasonable promise of becoming doctors and dentists are inducted prior to becoming eligible for commissions

War industries are undergoing a hitherto unknown expansion Aeronautical, civil, electrical, chemical, mining metallurgical mechanical and radio engineers together with physicists and chemists are essential to insure a sufficient flow of material for

the armed forces, and industry must look to the engineering, chemical and physics students now in training to meet their present and future requirements

It is equally important that instructors in these fields be seriously considered for occupational deferment Shortages of qualified instructors are known to exist The educational institution employing the instructor should be requested to file DSS Form 42A in all cases in which deferment is sought

In considering student deferment cases, certain local boards are requiring the execution of DSS Form 42A in addition to the affidavit of the college or university contained in Bulletin No 10 issued by the American Council on Education DSS Form 42A should not be required when the American Council on Education affidavit has been submitted

Local boards will be informed when the manpower requirements necessary to the national health safety or interest and war production become static Until such time, the policy set forth in the Memoranda to All State Directors I 62, I 91, I-99 and I-150 remains in force

LEWIS B HERSHEY, Director

MAN POWER OF THE NATIONS AT WAR

On the basis of volume of man power of fighting age, the United States and its allies would have a two to one chance of victory according to an estimate of war age males in the belligerent countries made by the United States Bureau of the Census, Department of Commerce

Allies—Males Aged 18 35 as of July 1, 1941
(Estimated)

United States	
Continental United States	19 914 000
The Philippines	2 400 000
Other U S territories and possessions	482 000
Total U S and possessions	22 796 000
Great Britain and Dominions	
United Kingdom	6 815 000
Australia	1 083 000
Canada	1 797 000
New Zealand (excluding Maoris)	238 000
Union of South Africa (white)	340 000
Total Great Britain and Dominions (excluding India)	10 273 000
(India had an estimated 58 244 000 males between 18 and 35 as of July 1 1941 and if India should be included the total for Great Britain and its dominions would be	
	68 517 000
Russia	
Russia (Europe and Asia)	21 574 000
China	
If it was possible to mobilize the full strength of China's 18 35 age group of males there would be added to the Allies strength approximately	
	49 000 000
Total Allies (18 35 males) not including India and China	56 643 000
Total Allies (18 35 males) including India and China	163 887 000
NOTE—Because of the incomplete census records respecting the natives of the Netherlands Indies the U S Census Bureau did not undertake to estimate its 18 35 male population Its total male and female population of all ages is estimated at 69 435 000	
Axis Nations—Males Aged 18 35	
Germany (including Austria and Sudetenland)	11 261 000
Italy	7 440 000
Japan (excluding Korea and Manchukuo)	10 839 000
Total Axis Nations	29 540 000

The Census Bureau compilation indicates that the principal belligerents by making fighters of all males between the ages of 18 and 35, would be able to place 85 203 000 men in the field not including China India and the Netherlands Indies Of the grand total, 56 643 000 would serve under allied flags and 28 560 000 under Axis flags

If China and India were to be included the number of fighting males between 18 and 35 in the allied nations would aggregate 163,887,000

The analysis of the Census Bureau was made from the latest censuses of all the nations involved with projections brought forward to July 1, 1941 The figures do not take into account casualties already suffered but these would not seriously disturb the ratio

The estimates likewise do not include, on either side, the males of 18 to 35 in the occupied countries of France, Czechoslovakia, Denmark, Estonia, Greece, Latvia, Lithuania, Netherlands, Norway, Poland, Yugoslavia and French Indochina, whose total population, male and female of all ages, is 167,978,000.

CIVILIAN COOPERATION AT HONOLULU AND PEARL HARBOR

Hundreds of lives are reported to have been saved following the December 7 attack on Honolulu and Pearl Harbor through the use of the adequate supply of blood plasma and other blood substitutes made immediately available to the Army and Navy by the civilian defense group of Honolulu, which was part of a prearranged plan set up by the Army department surgeon Col. Edgar King, who had requested also the civilian medical group to organize surgical teams for army service. The head of the Civilian Plasma Bank of Honolulu was Dr. Forrest J. Pinkerton. Immediately after the bombing started, the wives of officers and enlisted men rushed to Hickam Field Hospital to aid the few nurses on duty at the time, where they did heroic work in the hospital kitchens and in making bandages and surgical dressings. The main army post kitchens having been blasted by bombs, the Hickam Field Hospital kitchens for a while fed fifteen hundred persons daily. This information was brought to light in a report to the Surgeon General of the Army by Dr. Perrin Long of Johns Hopkins University Medical School, Baltimore, and Dr. I. S. Ravdin of the University of Pennsylvania School of Medicine, Philadelphia. The report stressed the speedy transfer of the wounded to the U. S. Army Tripler General Hospital, the splendid cooperation of the civilian defense group, and the incalculable value of the sulfonamide treatment of wounds following the Japanese attack. They said: "We have been impressed again and again with the incalculable value of sulfonamide therapy in the care of many of the casualties," the report states. "We believe that it is highly important that physicians—both civilian and military—become familiar with the general and specific considerations which govern the use of oral and local use of the sulfonamides in the treatment of wounds and burns and that, so far as it is possible, routine methods for the use of sulfonamides in casualties be devised and adopted. . . .

"The Committee on Chemotherapy and the Committee on Wound Infection should receive information on the startling efficacy of sulfonamide therapy in the open wounds."

BASE HOSPITAL NO. 17 REORGANIZED

Base Hospital No. 17, which served during the first world war, comprising members of the staff of Harper Hospital, Detroit, is being reorganized for service in the present war under the command of Col. Henry R. Carstens, president of the Michigan State Medical Society. Dr. Louis J. Hirschman will be chief of the surgical service and Dr. E. D. Spalding chief of the medical service. These three medical officers served in the first world war. Other physicians already assigned to the present unit are Majors Douglas Donald, Charles E. Lemmon and Lowell B. Ashley, Capt. John Tulloch and S. G. Meyer, and Lieuts. George T. McKean and Don M. Murphy. The skeletonized organization will eventually comprise at least forty-two physicians. In the first world war the Harper Hospital unit was headed by Dr. Angus McLean and served first as a Red Cross unit and later as an army unit at Dijon, France, from which point some of its units saw service in the front lines.

DAYTON SPECIALIST UNIT ORDERED TO ACTIVE DUTY

Six of the nine members comprising the Medical Specialist Unit of Dayton, Ohio, were ordered to report for active duty at a naval hospital on January 12. The members of the unit who received orders were Commander Walter M. Simpson, an internist, director of the laboratories at Miami Valley Hospital, Dayton; Lieut. Commanders Harry R. Huston, a surgeon; Marion W. Coleman, a urologist; James L. Sagebiel, a neuro-

psychiatrist; Jerome Hartman, an orthopedic surgeon, and Arthur M. Culler, an ophthalmologist. This unit comprises six nurses also. During his absence Dr. Simpson's place as director of the laboratories at Miami Valley Hospital will be taken by Dr. Melvin Oosting, assistant director of laboratories, and Dr. Simpson's position as director of the medical research at the Kettering Institute will be taken by Dr. H. Worley Kendell, assistant director. This Dayton unit was organized in 1934 at the suggestion of the Surgeon General of the Navy and, although one of the first organized, is now one of many similar medical units.

HAWAII NEEDS MEDICAL SUPPLIES

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, says that an urgent appeal has been received from Queens Hospital, Honolulu, for drugs and instruments with which physicians may help take care of existing casualties. Among the things needed as indicated by the list furnished by the committee are catgut and silk sutures, Luer syringes of various sizes, hypodermic needles, cotton, gauze, bandages and drugs, including unguentine, boric acid ointment, gentian violet powder, rubbing alcohol, phenobarbital, soluble, pentobarbital, procaine hydrochloride, nikethamide, sulfanilamide, sulfathiazole, epinephrine and tetanus antitoxin. Arrangements have been made for the free transportation of these articles from various points in this country to Hawaii by truck, steamer and plane.

NAVY RECOGNIZES ALLERGY AS A SPECIALTY

The commanding officer of the U. S. Naval Medical School, Washington, D. C., recently recommended that allergy be officially recognized as a specialty in the Navy and that post-graduate training in the subject be instituted. The advisory board considered the recommendation and the Surgeon General of the Navy approved it. Arrangements are being made with various medical colleges and with some well known allergists in private practice to provide instruction in this subject to selected naval medical officers.

REAR ADMIRAL STITT AWARDED THE THEOBALD SMITH MEDAL

At the recent annual meeting of the American Academy of Tropical Medicine in St. Louis, Rear Admiral E. R. Stitt, M. C., U. S. Navy, was awarded the Theobald Smith gold medal of the George Washington University, Washington, D. C. Admiral Stitt, a former surgeon general of the U. S. Navy and former president of the Association of Military Surgeons of the United States, is the author of a well known book on tropical medicine and of another on laboratory procedures.

GOVERNMENT TO PROVIDE SOLDIERS WITH SPECTACLES

The War Department announced on January 18 that the army will provide all persons in the military service with spectacles when required and will replace lenses and frames when damaged or lost in the performance of military duty. These spectacles will conform to specifications to be issued by the Surgeon General of the Army. Individuals desiring a different kind must pay for them.

PURCHASE FOUR MILLION SHOES IN MARCH

After conferences in Washington between shoe manufacturers and the U. S. Army quartermaster procurement officers, it was estimated that during March and April the Army will purchase about two million pairs of shoes and that later the purchasing plans will be revised to still higher figures. The shoe manufacturers at present have ample capacity to increase their shoe production to the desired level without increase in factory facilities. The foregoing rate of purchase is about twice that of the Army at present.

PROPERTY OF THE
HOUSE COMMITTEE

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY

FIRST CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, First Corps Area, which comprises the states of Maine, Vermont, New Hampshire, Rhode Island, Massachusetts and Connecticut:

BORENSTINE, Joseph, 1st Lieut, Boston, Fort Devens, Mass
COULINS, Ray W., Jr., 1st Lieut, Colchester, Vt, Fort Adams, R I
DOUCET, Charles S., Lieut Colonel, Central Falls, R I, Camp Lee, Va.
DUENNEBIER, Harold W., 1st Lieut, Hartford, Conn, Windsor Locks, Conn
DUNBAR, Clarence E., Lieut Colonel, Manchester, N. H., Camp Lee, Va
GRULEE, Clifford G., Jr., 1st Lieut, Boston, Fort Devens, Mass
HASELHORN, Donald H., 1st Lieut, Springfield, Mass, Army Air Base, Manchester, N H
KEES, Philip A., Captain, Longmeadow, Mass, Westover Field, Mass.
KREIDBERG, Marshall B., 1st Lieut, Boston, Bangor, Maine
LARSON, Karl V., 1st Lieut, Machias, Maine, Camp Lee, Va

LEVIN, AARON H., 1st Lieut, Newton Center, Mass, Fort Devens, Mass
LONG, Norman G., Captain, Lowell, Mass, Fort Banks, Mass
MAECK, John VanS., 1st Lieut, Shelburne, Vt, Fort Devens, Mass
NEFF, Richard S., 1st Lieut, Boston, Fort Devens, Mass
RECORD, Eugene E., 1st Lieut, Boston, Fort Devens, Mass
SCRIBNER, Robert A., 1st Lieut, Haverhill, Mass, Camp Edwards, Mass
STANLEY, Howard W., 1st Lieut, Worcester, Mass, Camp Lee, Va
SUTCH, Gabriel C., 1st Lieut, Howard, R I, Fort Devens, Mass
WINDUS, Charles E., 1st Lieut, New Haven, Conn, Bangor, Maine
WITTE, Max E., Captain, Bangor, Maine, Fort Devens, Mass

Orders Revoked

CORRIGAN, Francis V., 1st Lieut, Providence, R I

Relieved from Active Duty

CAREY, Francis G., 1st Lieut, Rochester, Mass
LEVIN, Spencer E., Captain, Boston
ROBEY, Nathaniel C., Captain, Newton Center, Mass
ZENTGRAF, Leo P., 1st Lieut, Manchester, Mass

SECOND CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Second Corps Area, which comprises the states of New York, New Jersey and Delaware:

BRENNER, Joel Jerome, 1st Lieut, Brooklyn, Camp Upton, N. Y
BREZINSKI, Edward, 1st Lieut, Perth Amboy, N. J., Fort Jay, N. Y.
COMDEN, Nathaniel, 1st Lieut, New York, Camp Croft, S C

CORTESE, Joseph T., 1st Lieut, Newark, N. J., Fort Bragg, N. C.
HARTSTEIN, Edward, 1st Lieut, Brooklyn, Fort Dix, N. J.
KAPLAN, Harry, 1st Lieut, New York, Fort Dix, N. J.
KELLEY, Wayne, 1st Lieut, Leonardsville, N. Y., Camp Lee, Va
KING, Walter G., 1st Lieut, Binghamton, N. Y., Pine Camp, N. Y.
O'BRIEN, Kennedy W., 1st Lieut, Astoria, N. Y., Fort Sereven, Ga
RUBBONE, Mario, 1st Lieut, Astoria, L. I., N. Y., Fort Dix, N. J.
STRINGER, Sydney, Captain, Syracuse, N. Y., Fort Monmouth, N. J.
WIESEN, Arnold Maxwell, 1st Lieut, Riverhead, N. Y., Camp Upton, N. Y.

Orders Revoked

MAZZA, Peter A., 1st Lieut, Mount Vernon, N. Y.
NIEMAN, Solomon Z., 1st Lieut, New Brunswick, N. J.
RHOADS, Harmon T., Jr., Captain, New York
ROSENBERG, Albert B., Captain, North Plainfield, N. J.
SATIR, Samuel S., 1st Lieut, Jackson Heights, N. Y.
SAMUELS, Sol L., 1st Lieut, Plainfield, N. J.
SOLOVAY, Hyman, 1st Lieut, Brooklyn
THORNE, Irving J., 1st Lieut, New York

THIRD CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Third Corps Area, which comprises the states of Pennsylvania, Virginia, District of Columbia and Maryland:

BIANCARELLI, Edmund Joseph, 1st Lieut, Jessup, Pa, Fort Belvoir, Va
BUCKLEY, Michael Lester, 1st Lieut, Arlington, Va, Fort Story, Va
COBERN, Charles Blair, 1st Lieut, Washington, Pa, Carlisle Barracks, Pa
COTTER, John Joseph, 1st Lieut, West Wyoming, Pa, Aberdeen Proving Ground, Md
DE MEULES, Edgar A., 1st Lieut, Philadelphia, Fort Belvoir, Va
DIFRANCESCO, Vincent James, 1st Lieut, Washington, D. C., Fort Eustis, Va
DRAYER, Calvin Searle, Captain, Upper Darby, Pa, Camp Lee, Va
DRIVER, Samuel Francis, 1st Lieut, Troutville, Va, Holabird Quartermaster Depot, Baltimore
EASTHAV, John Philip, 1st Lieut, Culpeper, Va, Indiantown Gap Military Reservation, Pa
EISNER, Abraham G., 1st Lieut, Scranton, Pa, Aberdeen Proving Ground, Md
FARLEY, Otis Rhanor, 1st Lieut, Washington, D. C., Carlisle Barracks, Pa
FARRELL, George Raymond, 1st Lieut, Washington, D. C., Indiantown Gap Military Reservation, Pa
FINGEGAN, Eugene F., 1st Lieut, Washington, D. C., Edgewood Arsenal, Md
GAY, James Rowland, 1st Lieut, Baltimore, Fort George G. Meade, Md
GOULD, Ernest Alva, 1st Lieut, Washington, D. C., Aberdeen Proving Ground, Md
HAFT, Abraham Seamor, 1st Lieut, Washington, D. C., Carlisle Barracks, Pa
HEIM, Hugh Wilson, 1st Lieut, Schuylkill Haven, Pa, Camp Lee, Va

JOHNSON, Robert Chester, 1st Lieut, Allison, Pa, General Dispensary, U. S. Army, Philadelphia
JONES, Clement Russell, Jr., Captain, Dixmont, Pa, Fort Belvoir, Va
KIEHL, Paul Victor, 1st Lieut, Drexel Hill, Pa, General Dispensary, U. S. Army, Baltimore
LUKAS, Alexander Benjamin, 1st Lieut, Shenandoah, Pa, Indiantown Gap Military Reservation, Pa
MCLEE, Carlisle Emerson, Jr., 1st Lieut, Pittsburgh, Fort Eustis, Va
McLAIN, Paul Lrimer, Captain, Pittsburgh, Camp Lee, Va
MESSMORE, Isaac Lindsey, 1st Lieut, Mantonown, Pa, Carlisle Barracks, Pa
MOORMAN, John Hope, Jr., 1st Lieut, Harrisonburg, Va, Fort Eustis, Va
MULDAWER, Milton Earl, 1st Lieut, Philadelphia, Carlisle Barracks, Pa
OMEARA, Thomas Joseph, 1st Lieut, Swissvale, Pa, Aberdeen Proving Ground, Md
PEARCE, Leroy Sannoner, 1st Lieut, Farmville, Va, Edgewood Arsenal, Md
PEKIN, Thomas Joseph, 1st Lieut, Washington, D. C., Camp Lee, Va
PLUMER, Joseph Neilson, 1st Lieut, Cresson, Pa, Fort Eustis, Va
PORTER, Edgar Lee, 1st Lieut, Embreeville, Pa, General Dispensary, U. S. Army, Philadelphia
ROBINSON, William Herbert, III, 1st Lieut, Roaring Spring, Pa, Fort George G. Meade, Md
SCHROEDER, Alfred Richard, 1st Lieut, Washington, D. C., Aberdeen Proving Ground, Md
SPAIK, Richard R., Colonel, Mechanicsburg, Pa, Fort Devens, Mass
SULLIVAN, Herbert Hilary, Lieut Colonel, Pittsburgh, Camp Lee, Va
TANKIN, Louis Haberer, 1st Lieut, Baltimore, Edgewood Arsenal, Md
WATSBROT, Edward Louis, 1st Lieut, Philadelphia, Fort Eustis, Va
WEINER, Marcus Allen, 1st Lieut, Washington, D. C., Carlisle Barracks, Pa
WOOD, Rowland Emery, 1st Lieut, Philadelphia, Fort Eustis, Va

Orders Revoked

MASLAND, Richard Lambert, 1st Lieut, Philadelphia
SETTIF, William Booth, Captain, Baltimore

PENZ, George Henry, 1st Lieut, Pittsburgh
HENDERSON, Charles Henry, Captain, Newton, Va

ORGANIZATION SECTION

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Bill Introduced.—H. R. 6399, introduced by Representative Randolph, West Virginia, proposes to authorize the appropriation of such sums as may be necessary to enable the commissioners of the District of Columbia to provide for the accommodation, in addition to existing capacity, of 1,000 bed patients in hospitals operated by the District of Columbia.

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 2217 has been reported to the Senate, providing that during the present war personnel of all components of the Army may be detailed as students at technical, professional and other educational institutions or as students, observers or investigators at industrial plants, hospitals and other places. H. R. 6293 has been reported to the House, proposing to establish a Women's Army Auxiliary Corps for non-combatant service with the Army of the United States. H. R. 6430 has passed the House, making appropriations for the Executive Office and sundry independent executive bureaus, boards, commissions and offices for the fiscal year ending June 30, 1943. This bill contains an item of \$4,557,000 for hospital and domiciliary facilities for veterans.

Bills Introduced.—S. 2188, introduced by Senator Reynolds, North Carolina, contemplates the appointment of an officer of the Veterinary Corps as assistant to the Surgeon General of the Army with the rank of brigadier general. S. 2201, introduced by Senator Capper, Kansas, provides that in any case in which the production of a birth certificate is required under any provision of law in connection with the employment of any person by any executive department or other governmental agency, and such birth certificate either cannot be obtained or cannot be obtained without unreasonable delay, proof of the birth of such person satisfactory to the department or agency concerned may be accepted in lieu of the production of the birth certificate. H. Res. 409, submitted by Representative Barry, New York, proposes to create a select committee to be composed of five members of the House of Representatives to investigate the manner in which deferments have been granted under the Selective Training and Service Act of 1940 with a view to determining whether or not the policy of Congress with respect to such deferments is being properly and uniformly applied.

STATE MEDICAL LEGISLATION

Kentucky

Bills Introduced.—H. 95 proposes to enact a new pharmacy practice act which, among other things, proposes to limit the sale and distribution of drugs and medical supplies to pharmacies operating under permits issued by the board of pharmacy. The term "medical supplies," as used in the bill, is defined to include absorbent cotton, bandages, gauze, sutures, compacts, compresses, surgical dressings and other products and appliances used in the diagnosis, cure, mitigation, treatment or prevention of disease. The bill, if enacted in its present form, would seem to cast serious doubt on the legal right of a licensed physician to dispense, and possibly to use, drugs or medical supplies with respect to his own patients. H. 96 proposes to enact what is cited as the Kentucky Food, Drug and Cosmetic Act to regulate the manufacture, sale, distribution and advertising of foods, drugs, cosmetics and therapeutic devices.

Mississippi

Bill Introduced.—H. 205 proposes to condition the issuance of a license to marry on the presentation by each party to the proposed marriage of a physician's certificate as to the absence of any contagious disease in the party.

New Jersey

Bills Introduced.—A. 9 proposes, apparently, to repeal the medical practice act. A. 41 proposes to authorize the board of chosen freeholders of any county of the second class to create the office of county chief medical examiner. The bill proposes that when any person shall die as a result of violence, or by casualty or suicide, or suddenly when in apparent health, or when unattended by a physician, or within twenty-four hours after admission to a hospital, or in prison, or in a suspicious or unusual manner, the police department of the municipality in which he died, or the superintendent or medical director of the institution in which he died, or the physician called in attendance, shall immediately notify the office of the chief medical examiner and it is then to be the duty of the chief medical examiner to investigate fully the circumstances of the death.

New York

Bills Introduced.—S. 312 proposes to enact a new law regulating the manufacture, sale, distribution and advertising of foods, drugs, cosmetics and health devices. A. 308, to amend those provisions of the medical practice act relating to the practice of physio-therapy, proposes that any person holding a registered license to practice physio-therapy who on the submission of proper credentials satisfies the regents that he has sufficient training or experience may be granted the right to use the physio-therapy modalities of actinotherapy, hydrotherapy, mechanotherapy, thermotherapy and electrotherapy, exclusive of the x-ray, without the supervision of a duly licensed physician. A. 388 proposes to require every local board of health and every health officer to exercise proper and vigilant medical inspection of all persons, 21 years of age or over, infected with poliomyelitis, and, after approval by the state commissioner of health, provide at the remedial stages of the disease surgical, medical or therapeutic treatment or hospital care, and necessary appliances and devices for persons so infected or exposed who cannot otherwise be provided for. One half of the cost of providing such treatment, care and appliances is to be made a charge against the county, or the city of New York, as the case may be, in which the afflicted person resides, and the other one half of the cost is to be paid for by the state. A. 493 proposes to require every physician immediately to give notice to the health officer of the county, city, town or village wherein he resides of every case of infantile paralysis under his care, provided that when such cases occur in districts of less than fifty thousand population not having a whole time health officer or in state institutions, such cases are to be reported directly to the state department of health or its district health officer. A. 504, to amend the workmen's compensation act, proposes to require an employer to provide for the hospitalization of an employee mentally disabled as the result of an accident arising out of and in the course of his employment. S. 215 and A. 226 proposes to create a temporary state commission to make a study of the prevalence, causes and effects of hay fever and kindred ailments and to devise and recommend remedial procedures and legislation designed to effect their treatment, cure and ultimate elimination.

Virginia

Bills Introduced.—S. 16 proposes that, whenever in a civil or criminal proceeding issues arise on which the court deems expert evidence desirable, the court may, on its motion or on the motion of either party, appoint one or more experts, not exceeding three, to testify at the trial. H. 28 proposes to authorize designated state officials and judges to consent to the surgical and medical treatment of persons under 21 years of age who are separated from the custody of their parents or guardians and

are in need of surgical or medical treatment. H. 40 proposes to authorize the respective governing boards of the Medical College of Virginia and of the University of Virginia to establish four annual medical scholarships each, each scholarship to be of an annual value of \$550. A person receiving such a scholarship must agree to pursue the medical course of the school awarding this scholarship until his graduation and, after graduating and completing a term of not exceeding two years as an intern at some approved hospital or institution, to engage continually in the general practice of medicine in a rural community in the state of Virginia, selected by the state health commissioner, for a period of years equal in number to the years that he has been or shall be a beneficiary of the scholar-

ship. H. 51, to supplement the medical practice act, proposes, except as is otherwise provided in the section of the act relating to exemptions, that no person shall practice medicine in any of its branches in the state without a valid, unrevoked certificate or license authorizing such practice issued by the state board of medical examiners and duly recorded as required by law. H. 52 proposes to authorize any court of record having chancery jurisdiction to enjoin and restrain any person from practicing medicine in any of its branches in the state without a valid, unrevoked certificate or license authorizing such practice issued by the state board of medical examiners and duly recorded as required by law.

MEDICAL ECONOMIC ABSTRACTS

THE NATION'S HEALTH

In spite of all the pessimistic outpourings on health conditions, Dr. S. S. Goldwater took a decidedly optimistic outlook in an address before America's Town Meeting of the Air, Dec. 4, 1941. Some of the more significant points brought out in this address are quoted or summarized in the following:

In public health circles it has become the fashion, partly on the basis of loosely compiled statistics of physical defects, to picture the United States as a decadent and decrepit nation. We are told that we are a toothless, almost sightless, people, that we have flat feet, flabby muscles and weak minds. We are warned that we are undernourished, that our vital organs are degenerating, that we are no match for the germs of disease that are within us and all about us.

I refuse to subscribe to this doctrine of despair, for it is a doctrine founded on half truths. It is true that physical defects are common among us, but many of the defects that are used in the compilation of alarmist statistics are only minor defects. Modest doctors of medicine and public health officers often present their depressing tabulations with an apologetic air. Now while it is true that medicine has not yet solved the problem of the common cold and that public health administration is not yet able to guarantee perfect living and working conditions, both professions have accomplished such wonders that an attitude of abject humility ill becomes them. I take off my hat to them!

The familiar indictment asserts that private medical practice, the voluntary hospital system and local health administration have failed. It is implied that medical care must be administered by government, since government alone is in a position to promise that no preventable illness will be disregarded, that

no sick person will be neglected, that no imperfection in medical technique will be tolerated.

I am ready to acknowledge the difficulty of immediately providing prompt and sufficient private medical care for all regions and all classes, but I believe in the practicability of substantial further progress under private and local initiative and control. Although government aid may be required, the limits of self help have not been reached.

There are many hopeful signs. Medical education is improving all the time. A great number of first class hospitals are engaged in research. The unsolved problems of medicine are under constant attack. Hospital administration has been systematized. Many cities and some states are now well supplied with hospital beds. Health centers are rapidly multiplying. Farmers are banding together to secure needed medical service. Industry is subjecting itself to more rigid health supervision. Employers are cooperating with their employees in providing medical care. Housing reform is now an accepted public policy. Discoveries concerning nutrition have made it possible to plan for the better distribution and the wiser use of food. Infant mortality is at a new low. Childbirth has lost most of its terrors. The significance of planned parenthood is understood. Tuberculosis slowly declines. The utilization of hospitals is increasing. Dentistry is being brought into proper focus with medicine. Public health nursing is expanding. Outpatient services are improving. Home medical service is being provided for families on relief.

For the great mass of regularly employed low income workers, a powerful economic barrier to prompt hospital care can be removed by the wider development of voluntary prepayment plans for group hospitalization and related medical care. Such plans, though still in their infancy, already provide hospital service, when needed, for nearly eight million persons.

WOMAN'S AUXILIARY

Georgia

The Woman's Auxiliary to the Fifth District Medical Society held its semiannual meeting, recently, at the Crawford W. Long Hospital in Atlanta. Mrs. J. Harry Rogers, district manager, presided. Among the guests were Mrs. Lee Howard, Savannah, and Mrs. J. Lon King, Macon, president and president-elect respectively of the Woman's Auxiliary to the Medical Association of Georgia; Mrs. W. A. Selman, Atlanta, vice president of the state group; Mrs. Eustace Allen, Atlanta, chairman of revisions for the national group; Mrs. Olin Cofer, councilor from Georgia to the Woman's Auxiliary to the Southern Medical Association; Mrs. Allen Bunce, wife of the president of the Medical Association of Georgia; Mrs. C. W. Roberts, wife of the president of the Fifth District Medical Society, and Mrs. Murdock Equen, president of the Woman's Auxiliary to the Fulton County Medical Society.

Dr. Roberts introduced Dr. Allen Bunce, who spoke on "The Future of Medicine in Georgia." Mrs. King talked on the part that the physician's wife must play in national defense, and

Mrs. Howard stressed the problems of the auxiliary. Mrs. Jeff Richardson, chairman of health films in the Fifth District, told of her plans for this project.

The wives of army physicians stationed at the various hospitals or camps in the vicinity of Atlanta were honor guests at the meeting of the Woman's Auxiliary to the Fulton County Medical Society, recently, at the nurses' home of Crawford W. Long Hospital, Atlanta. Mrs. Murdock Equen, president, presided. Colonel Cooley spoke of Lawson General Hospital, which cares for soldiers throughout the area. Dr. Edgar H. Greene, medical director of selective service for Georgia, exhibited a chart showing the causes for which draftees were rejected.

Tennessee

The newly elected president of the Woman's Auxiliary to the Rutherford County and Stone's River Academy of Medicine, Mrs. S. B. Smith, presided over a recent meeting at the home of Mrs. B. W. Rawlings. Mrs. G. B. Thackston, a guest, spoke on "America in a Postwar World."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ALABAMA

Regional Meeting.—The Northwestern Division of the Medical Association of the State of Alabama met at the Negley Hotel, Florence, January 28 for the following program

Dr John J Shea Memphis, Tenn, The Management of Fractures of the Face
Dr William J B Owings Brent Polymyositis A Personal Experience.
Dr Seale Harris Birmingham, The Food Factor in Winning the War
Dr Ralph C Benson Birmingham Simplicity in Gynecologic Practice
Dr William H Spruiell Russellville, Fascia in Hernial Repair

ARKANSAS

New Specialty Group.—The Arkansas Society of Obstetrics and Gynecology was organized at a meeting in Little Rock on December 18 with the following officers Drs Ernest H White, Little Rock, president, Clyde D Rodgers, Little Rock, vice president, and Ruth Ellis Lesh, Fayetteville, secretary-treasurer

Hospital News.—St Edward's Mercy Hospital, Fort Smith, believes that the past year was a record one for an institution of its size and type The hospital has a normal capacity of one hundred beds and sixteen bassinets and is classified as general In the past year there were 3,857 admissions and 586 babies delivered The federal government has recently approved a \$90,000 grant to assist in a \$200,000 expansion program

Society News.—The Ninth Councilor District Medical Society was addressed in Harrison, December 3, by Dr Arthur F Hoge, Fort Smith, among others, on "Cirrhosis of the Liver"—Dr Joseph W Kelso, Oklahoma City, discussed "Repair of Third Degree Lacerations" before a recent meeting of the Pulaski County Medical Society, guests of honor at this session were Dr Herbert Fay H Jones, Little Rock, president of the state medical society, and Drs Melvin E McCaskill Little Rock, Merriman L Norwood, Lockesburg, William T Wootton Hot Springs National Park, Frank Vinsonhaler, Little Rock, Oscar J T Johnston, Batesville, and Albert S Buchanan, Prescott, past presidents of the state society—Dr Roy E Schirmer, Fort Smith, addressed the Sebastian County Medical Society, December 9, on control of venereal diseases

CALIFORNIA

Equine Encephalomyelitis and Mosquito Control.—The twelfth annual conference of the California Mosquito Control Association was held at the University of California at Berkeley, December 15-16 A symposium on equine encephalomyelitis was presented by the following

William B Herms, A M professor of parasitology and entomologist in the experiment station at the University of California, Berkeley, Introduction
Beatrice F Howitt A M associate in research medicine University of California Medical School San Francisco Relationship of Equine Encephalomyelitis and St Louis Encephalitis to Man and Animals in California
William C Reeves, B S division of entomology and parasitology, University of California Medical School, Newer Developments in Knowledge of Insect Hosts and Vectors
Dr William McD Hammon George Williams Hooper Foundation, University of California Medical School, San Francisco, Host Animals of Virus Encephalitis

Speakers in a symposium on mosquito control and national defense were

Dr Bertram P Brown San Francisco director of the state department of public health Introduction
Stanley B Irechorn Ph D, professor of entomology and assistant dean of the College of Agriculture University of California Berkeley, Military Mosquito Control in World War I
Dr Richard H Creel, medical director, U S Public Health Service San Francisco Federal Aid in Mosquito Control Work
I C Peters B S in charge of mosquito control bureau of sanitary engineering California department of health, Mosquito Breeding and Control in Vicinity of Military Zones

A banquet session was addressed by Dr Alfred C Reed professor of tropical medicine at University of California Medical School, San Francisco, on "Problems Involved in Control of Mosquito Borne Diseases Under Tropical Conditions" The second day's program was largely devoted to a "Review of Literature on Mosquitoes for 1940-1941"

COLORADO

Correction—Refresher Courses.—The Colorado State Medical Society will offer a series of refresher courses in Denver on February 16-18 instead of on February 16-17 as was announced in THE JOURNAL, January 24, page 309

Midwinter Postgraduate Clinics.—The tenth annual Midwinter Post Graduate Clinics of the Colorado State Medical Society will be held in Denver, February 19-21 Guest speakers will include

Dr John A Toomey, Cleveland Chemotherapy in Infectious Diseases
Dr Harold O Jones Chicago Management of Pelvic Infections
Dr Benjamin H Orndoff Chicago Endometriosis Its Relation to Sterility and Other Conditions of the Female Pelvis
Dr Carl M Peterson, Chicago Secretary, Council on Industrial Health, American Medical Association, Industrial Health Progress and Reports
Dr Edward H Hashinger, Kansas City, Mo, Hypothyroidism
Dr John Henderson, Philadelphia Human Plasma A Review of Its Preparation and Indications in Military and Civil Practice
Dr Ozro T Woods, Dallas, Texas Care of the Critically Ill Patient
Dr Charles B Huggins Chicago, Endocrine Relationships in Carcinoma of the Prostate
Dr Oliver E Van Alvea Chicago Treatment of the Acute Antrum
Dr James S Speed Memphis Tenn Treatment of Compound Fractures

In addition there will be a guest speaker from the army medical corps to discuss some subject in military medicine. All guest speakers will conduct clinics The annual dinner dance will be held Saturday evening at the Shirley-Savoy Hotel

CONNECTICUT

Meeting on Maternal Care.—Physicians in the Naugatuck Valley and the bureau of child hygiene of the state department of health held a dinner meeting, January 29, to discuss maternal care The speakers were Dr Joseph H Howard, Bridgeport "Relationship of the State Medical Society to the Public Health Program in Connecticut", Dr Stanley H Osborn, Hartford, "Plan of the State Department of Health for Improving Maternal Care in the State," and Dr Edwin F Daily, Washington, D C, "National Scope of Maternal and Child Health Program" The state health department has recently inaugurated a program in maternal care in the Naugatuck Valley area

Society News.—The Bridgeport Medical Society devoted its meeting in December to a symposium on peptic ulcer—The Norwalk Medical Society was addressed, January 14, by Edward T Buckingham LL B, compensation commissioner of Bridgeport, on "Compensation Medicine" The society was addressed, December 10, by Dr Paul Reznikoff New York, on "Importance of White Blood Cell Counts in Disease, Including Infections"—Dr Herbert F Traut, New York, presented the results of two and one-half years' study of vaginal smears after the method of Papanicolaou before the Hartford Medical Society on December 15—Dr Arthur M Fishberg, New York, discussed hypertension before the Waterbury Medical Society on December 11—The New Haven Medical Association was addressed, January 7, by Dr Bela Schick, New York, on allergy—Dr Champ Lyons, Boston, discussed chemotherapy before the New London County Medical Association in Norwich on December 4

DISTRICT OF COLUMBIA

Hospitals Subject to Tax.—According to the Washington Post, the Garfield Memorial and George Washington University hospitals, Washington, were returned to taxable status on January 10 The addition of these two hospitals brought the total of such institutions recently returned to tax rolls to nine The others are Emergency, Casualty, Sibley Memorial, Episcopal, Eye, Ear and Throat, Providence, National Homeopathic and Children's hospitals The report stated that the board of commissioners ruled that the institutions were not conducted as purely public charities without charge to inmates, and hence were not entitled to tax exemption It said that the Garfield Hospital has land and buildings assessed at more than a million dollars The nurses' school of the hospital will continue to enjoy tax exemption because it is an educational institution The paper stated that, although denying continued tax freedom for the George Washington University Hospital the commissioners ruled that the adjacent medical school building and its annex should continue on the free list The hospital received \$203,988 in 1940 Despite its description by university officials as a medical school 'teaching hospital,' this does not in the opinion of the board, affect its real status as a privately owned and privately conducted hospital

ILLINOIS

Society News.—Dr. Summer L. S. Koch, Chicago, discussed "Prevention and Care of Infections of the Hand" before the Sangamon County Medical Society in Springfield, December 4. —Dr. Stephen A. Zieman, Chicago, addressed the St. Clair County Medical Society in East St. Louis, January 8, on "Transversalis Fascia in Its Relationship to the Etiology and Repair of the Inguinal Hernia."

Chicago

The McArthur Lecture.—Dr. Isidor S. Ravdin, George Leib Harrison professor of surgery, University of Pennsylvania School of Medicine, and director of the Harrison Department of Surgical Research at the medical school, Philadelphia, will deliver the eighteenth Lewis Linn McArthur Lecture of the Frank Billings Foundation of the Institute of Medicine of Chicago, March 27. His subject will be "A Consideration of Some Problems of Biliary Tract Disease."

Branch Meetings.—The Douglas Park Branch of the Chicago Medical Society was addressed, January 20, by Drs. Russell D. Herrold on "The Sulfa Treatment of Gonorrhea" and Herbert Rattner, "The Five Day Treatment of Early Syphilis." —Dr. Chauncey C. Maher discussed "Cardiac Arrhythmia" before the Southern Cook County Branch, January 20. —At a meeting of the Irving Park Branch, January 27, Dr. Italo F. Volini spoke on "Sulfonamides with Special Reference to Pneumonia." —The Jackson Park Branch devoted its meeting, January 15, to a symposium on the sulfonamides. The speakers were Drs. Austin E. Smith, acting secretary, Council on Pharmacy and Chemistry, American Medical Association; Leander W. Riba, and Italo F. Volini. —Dr. Wesley W. Spink, Minneapolis, addressed the Northwest Branch, January 16, on "Present Status of Sulfonamide Therapy" and Dr. Chester C. Guy, "Sulfonamides in Surgery."

INDIANA

Changes in Health Personnel.—Dr. Harold J. Halleck, Winamac, was recently appointed health commissioner for Pulaski County for a term of four years. —Dr. Clifford H. Mayfield, Reynolds, has been reappointed health officer of White County for a four year term beginning January 1.

Physician Imprisoned for Defrauding Township.—Dr. Paul B. Arbogast, Vincennes, was recently sentenced to prison for from two to fourteen years for presenting false claims against the Vincennes township poor fund, it is reported. He was refused a suspended sentence and did not appeal the case. He is said to be serving his sentence.

Society News.—Dr. Joseph R. Crowder, Sullivan, spoke on "X-Ray Studies of the Chest" before the Sullivan County Medical Society in Sullivan, January 7. —The Fort Wayne Medical Society was addressed, January 20, by Dr. Samuel R. Mercer, Fort Wayne, on "Lupus Erythematosus" with presentation of clinical cases. —Drs. Joseph C. Lawrence Jr. and Harold D. Lynch, Evansville, discussed "Management of Acute Anterior Poliomyelitis" at a meeting of the Vanderburgh County Medical Society in Evansville, January 13. —Dr. Carl H. McCaskey, Indianapolis, addressed the Tippecanoe County Medical Society in Lafayette, January 13, on "Infections of the Vestibule of the Nose." —The Fountain-Warren County Medical Society's meeting, January 1, in Kramer was addressed by Dr. Marine R. Warden, Danville, Ill., on "Radiology." —Dr. Ernest R. Carlo, Fort Wayne, spoke on "Effect of War on Child Health" before the Whitley County Medical Society in Columbia City, January 13. —Dr. Bert E. Ellis, Indianapolis, discussed "Otitis Media and Mastoiditis," January 15, at a meeting of the Henry County Medical Society, Newcastle.

KANSAS

New Director of Local Health Service.—Dr. Henry H. Asher, Wichita, health officer of Sedgwick County for two years, has been appointed director of the division of local health of the state board of health, Topeka. Dr. John W. Turner, Marion, will be the new health officer of Sedgwick County.

Society News.—The Wyandotte County Medical Society was addressed, January 20, by Drs. William H. Algie on "Pneumonia" and Paul M. Krall, Kansas City, "The Sulfa Compounds in Therapeutics." —At a joint dinner meeting of the Kansas Obstetrical and Gynecological Society and the Sedgwick County Medical Society in Wichita, January 6, Dr. Willard M. Allen, St. Louis, spoke on "Clinical Use of Sex Hormones." Preceding this meeting Dr. Allen discussed "Significance of Abnormal Vaginal Bleeding."

LOUISIANA

Dr. Musser Resigns as President of State Board of Health.—Dr. John H. Musser, professor of medicine, Tulane University of Louisiana School of Medicine, New Orleans, has resigned as president of the state board of health, effective February 1, newspapers report, because his full time service would be required at the Tulane University Medical School. Gov. Sam H. Jones appointed Dr. Christopher L. Mengis, health officer of Iberia Parish health unit, New Iberia, as president of the state board. Early in 1941 Dr. Musser was in charge of a reorganization of the state board of health. Dr. Robert H. Onstott, U. S. Public Health Service, New Orleans, is executive officer of the board and Dr. Ford S. Williams, New Orleans, assistant state health officer. Dr. Mengis is a native of Vicksburg, Miss., graduating at Tulane in 1900. He has been connected with the state department of health since 1936, newspapers report, serving at one time as head of the division for crippled children.

MARYLAND

Personal.—Dr. Charles Reid Edwards, professor of clinical surgery, University of Maryland School of Medicine, Baltimore, has been appointed chief of emergency medical service for Maryland; the appointment was made on a recommendation by the Medical and Chirurgical Faculty of Maryland.

De Lamar Lectures.—The Johns Hopkins University School of Hygiene and Public Health, Baltimore, sponsored the following De Lamar Lectures: Dr. Karl F. Meyer, professor of bacteriology, and director, George Williams Hooper Foundation, University of California Medical School, San Francisco, "The Ecology of Plague," December 9, "The Ecology of Psittacosis," December 10 and Dr. Lowell T. Coggeshall, professor of epidemiology, School of Public Health, University of Michigan, Ann Arbor, "Immunity in Malaria," December 16.

MICHIGAN

Personal.—Dr. Clarence P. Lathrop, Hastings, was guest of honor at a meeting of the Barry County Medical Society, December 11, in recognition of his completion of fifty years in the practice of medicine. —Dr. and Mrs. Byron E. Burnell, Flint, observed their fiftieth wedding anniversary, December 30, with a reception to their friends. Dr. Burnell, who has been practicing in Flint since 1901, is a past president of the Genesee County Medical Society.

County Secretaries' Conference.—The Michigan State Medical Society conducted its annual county secretaries' conference at the Olds Hotel, Lansing, January 25. The speakers were:

- Dr. Andrew S. Brunk, Detroit, Progress Report on Michigan Medical Service.
- Hazen J. Payette, LL.B., Detroit, Physician's Income Tax.
- L. A. Potter, Lansing, Unity.
- Earl W. Munshaw, LL.B., Grand Rapids, Michigan's Intangible Tax Law.
- Mr. M. C. Smith, Lincoln, Neb., Design for a Statewide FSA Medical Program.
- Arthur A. Holmes, major, U. S. Army, Medical Procurement and Assignment.
- Don Leonard, Lansing, captain, Michigan State Police, England's Civilian Defense—An Eyewitness Account.
- Dr. Harold A. Furlong, Lansing, Emergency Medical Service in Community Defense.

New Director of Mental Hygiene.—Dr. Frank F. Tallman, clinical director of the Rockland State Hospital, Orangeburg, N. Y., has been appointed director of mental hygiene of the Michigan State Hospital Commission, Lansing. Dr. Tallman will have charge of the organization, supervision and coordination of the state child guidance clinic system; the establishment of an outplacement (boarding and colony) program; coordination and expansion of the hospital outpatient clinics in collaboration with the medical superintendents, with especial attention as to the preventive and parole aspects, and the development of an integrated statewide educational mental hygiene program. The state hospital commission is a seven member board charged with the responsibility of supervising and directing the state mental hospitals and of carrying on a program of prevention of mental illness. It is a separate and distinct agency of state government not connected with the state department of health, the department of public welfare or any other agency. Charles F. Wagg, Lansing, as the executive secretary of the commission, carries out its functions with respect to state hospitals. Dr. Tallman will direct the activities in the field of prevention. He graduated at the University of Alberta Faculty of Medicine, Edmonton, in 1927.

NEW JERSEY

Annual Meeting of Surgeons.—The Society of Surgeons of New Jersey held its annual meeting in Trenton, January 28. Rev. Alphonse M. Schwitala, S.J., dean of St. Louis University School of Medicine, St. Louis, was the speaker in the evening.

Society News.—Dr. Zacharias Bercovitz, New York, addressed the Bergen County Medical Society, January 13, on "Diagnosis and Treatment of Disorders of the Intestine."—The Morris County Medical Society was addressed in Morris Plains, January 15, by Dr. William Goldring, New York, on "Diagnosis and Treatment of Nephritis and Hypertension."—Dr. Tracy J. Putnam, New York, discussed "Epilepsy: Its Nature and Treatment" before the Atlantic County Medical Society on December 12.

NEW YORK

Graduate Courses.—January 20 marked the opening of a course in sulfonamide therapy, arranged by the state medical society and the state department of health for the Oneida County Medical Society at the Utica State Hospital, Utica. The series follows:

Drs. David D. Rutstein, Albany, Behavior of Sulfonamides in the Body and Principles for Their Use, and Joseph Ernest Del Monaco, Syracuse, Local and Internal Use of Sulfonamides in Surgery, January 20.
Drs. Thomas F. Laurie, Syracuse, Treatment of Genitourinary Infections in the Male, and Ferdinand J. Schoeneck, Syracuse, Sulfonamides in Obstetrics and Gynecology, January 27.
Drs. Joseph J. Bunim, Brooklyn, Treatment of Pneumonia, and Abraham Clement Silverman, Syracuse, Treatment of Meningitis, February 3.

A course in general medicine opened on February 3 for the Madison County Medical Society at the Hotel Oneida, Oneida. Dr. Eugene R. Marzullo, Brooklyn, spoke on "Practical Considerations of Blood Dyscrasias." On February 10 Dr. Milton B. Handelsman, Brooklyn, will discuss "Diabetes: Its Modern Interpretation and Treatment," and on February 17 Dr. Albert F. R. Andresen, Brooklyn, "Treatment of Gallbladder Disease." The state society and the state health department cooperated with the Onondaga County Medical Society in Syracuse in the following course:

Drs. Karl Jefferson Thomson, Mount McGregor, Behavior of Sulfonamides in the Body and Principles for Their Use, and Frank L. Meloney, New York, Local and Internal Use of Sulfonamides in Surgery, January 15.
Drs. Rolla R. Wolcott, passed assistant surgeon, U. S. Public Health Service, U. S. Marine Hospital, Staten Island, Treatment of Genitourinary Infections in the Male, and Charles H. Peckham Jr., Coopers-town, Sulfonamides in Obstetrics and Gynecology, January 22.
Drs. Norman H. Plummer, New York, Treatment of Pneumonia and Meningitis, and Frank Glenn and Harry Backwin, Panel Discussion, January 29.

New York City

Motion Picture on Treponema Pallidum.—Theodor Rosebury, D.D.S., assistant professor of bacteriology, Columbia University College of Physicians and Surgeons, showed a sound motion picture on Treponema pallidum at the New York Academy of Medicine February 3. Dentists, physicians, nurses and medical students were invited to attend.

Conference on Radiology.—The Eastern Conference of Radiologists was held at the Hotel Biltmore on January 23-24. Included among the speakers were:

Dr. Raymond L. Pfeiffer, Roentgenography of Exophthalmos.
Dr. Alexander B. Gutman, Biochemical Aids to Roentgenologic Problems in the Differential Diagnosis of Bone Disease.
Dr. Arthur F. Hunter, Roentgen Therapy of Keloids.
Dr. William E. Howes, Brooklyn, Agent
Dr. Harold Neuhoef, Circumscribed in Malignant Neoplastic Disease.
Dr. John M. Kenney, Radioactive
Dr. Cornelius P. Rhoads, Recent Studies in the Production of Cancer by Chemical Compounds.

Medical Bureau for Education Board Reorganized.—The medical division of the city's board of education has been reorganized to include a chief medical examiner and a part time psychiatrist. The action was approved at a meeting of the board on January 14. In addition there will be six part time medical examiners, a medical inspector aurist, a laboratory technician and a registered nurse, and a panel of psychiatrists. According to the New York Times the board appointed a committee to study the reorganization, at which time Dr. Emil Altman had been chief examiner. Since his retirement several months ago Dr. John E. Conboy has been acting chief examiner. The reorganization follows closely recommendations made by the New York Academy of Medicine, it was stated.

Hospital Services Increase Benefits.—The Associated Hospital Service has announced added benefits under its Three Cents a Day Plan, representing an annual increase of about \$1,000,000 in payments to hospitals. The discount allowance of 25 per cent of the hospital's regular charges for semiprivate

service, which has heretofore been granted after the initial twenty-one day period of full hospital service in any contract year, is increased to 50 per cent and extended to ninety days in any contract year. In maternity cases and conditions arising out of and during pregnancy the present credit of \$5 a day for a period of ten days will be increased to \$6 a day. The service also announced that \$1,500,000 has been set aside by the board of directors as a reserve to meet epidemic or war emergency demands. The plan's defense policy of continuing the enrolment privileges of men in the armed forces for whom medical care is temporarily the obligation of the federal government now applies to six thousand contracts. Under this policy, subscription charges are discontinued for single men and reduced for married men who wish to continue the protection of their families.

OHIO

Photographs of Physicians.—The families of the late Drs. Edwin M. Huston and Clement D. Smith, Dayton, have presented pictures of the physicians to the Montgomery County Medical Society, Dayton. Both physicians are past presidents of the society, which has a collection of pictures of all its former presidents. Dr. Huston was at one time president of the Ohio State Medical Society.

Director of Venereal Disease Control.—Dr. Harold J. Gordon, who has for a number of years been in charge of the venereal disease program of the Akron health department, has been appointed venereal disease control officer of the state department of health. At the time of his recent appointment Dr. Gordon was editor of the bulletin of the Summit County Medical Society and chairman of the committee on medical preparedness. He is a retired major of the army and was awarded the distinguished service cross for service overseas during World War I.

OKLAHOMA

"Your Health and You."—The Town Club of Oklahoma City is presenting a series of free health talks, with the approval of the Oklahoma County Medical Association, to acquaint the public with the best methods of prevention of disease and the promotion of health. All the speakers are from Oklahoma City:

Dr. John Walker Morledge, Health Problems Today and Tomorrow, November 5.
Dr. Charles P. Bondurant, What You Should Know About Cancer, December 3.
Dr. James Floyd Moorman, Colds, Influenza and Pneumonia, January 7.
Dr. Bert E. Mulvey, Heart Disease: Its Prevention and Care, February 4.
Dr. C. J. Fishman, The Brain in Health and Disease, March 4.
Dr. Bert F. Keltz, Your Weight and How to Control It, April 1.
A. C. Seids, D.D.S., These Teeth of Mine, May 5.
Richard H. Graham, Medicine on the March, June 3.

PENNSYLVANIA

Society News.—The Westmoreland County Medical Society devoted its meeting in Latrobe, February 3, to a symposium on treatment of compound fractures of the extremities; the speakers were Drs. Jack H. Hamill, Latrobe; William J. Potts, Richard S. Cole and Dennis R. Murdoch, all of Greensburg; Anthony L. Cervino, Jeannette, and Robert C. Johnston, New Kensington.

Philadelphia

Popular Science Talks.—"Science in War" is the theme of a series of seven lectures which opened on February 4 at the Philadelphia College of Pharmacy and Science with a talk by Ivor Griffith, Ph.M., entitled Health and the War. Other speakers will be:

Donald P. LeGalley, Ph.D., Physics in the War, February 11.
Freeman P. Stroup, Ph.M., Conservation, February 18.
Arthur Osol, Ph.D., Chemistry in the War, February 25.
George Rosengarten, Ph.D., Signals and Detectors, March 4.
Linwood F. Tice, M.Sc., Life Saving Medicines, March 11.
Louis Gershenfeld, Pharm.M., Bacteria and the War, March 18.

Pittsburgh

Society News.—The Allegheny County Medical Society was addressed in Pittsburgh, January 20, among others, by Dr. James S. Taylor, Altoona, on "Maternal and Fetal Mortality." A symposium on pneumonia constituted the meeting of the society, December 16; the speakers were Drs. William W. G. MacLachlan, John F. McCullough, George J. Kastlin, Pittsburgh, and Harrison F. Flippin, Philadelphia. —Dr. Samuel M. Dupertuis, among others, addressed the Pittsburgh Pediatric Society, December 19, on "Field of Plastic Surgery in Children." —Dr. Walter S. Nettrour, among others, discussed "Congenital Bronchoesophageal Fistula with a Case Report" before the Pittsburgh Surgical Society, January 16.

TENNESSEE

Health Units Merge.—The Memphis and Shelby County health departments recently consolidated with Dr. Lloyd M. Graves, Memphis, as the director. It was reported that the action was taken to reduce the city's budget. A contract was signed under which the county agreed to pay all expenses of the health service, it was stated.

Lectures at Meharry by Haven Emerson.—Dr. Haven Emerson, for many years professor of public health administration and director of the Institute for Public Health, Columbia University College of Physicians and Surgeons, New York, delivered a series of public lectures at Meharry Medical College, Nashville, December 2-3. His subjects were "Administrative Medicine for Care of the Sick and Public Health," "Natural History of Diphtheria in New York City from Its First Appearance to Date," "Alcohol as a Public Health Problem" and "Diabetes as a Problem of Preventive Medicine."

Society News.—Dr. Carrington Harrison, Nashville, discussed "Late Results in Treatment of Perforated Peptic Ulcer" before the Davidson County Medical Society in Nashville, January 13. The McMinn County Medical Society was recently addressed in Athens by Dr. William S. Muse, Knoxville, on "Kidney Complications Following the Use of Sulfanilamide and Its Derivatives." The Washington, Carter and Unicoi Counties Medical Society was addressed in Johnson City, December 4, by Dr. Milton Smith Lewis, Nashville, Tenn., on "Management of the Occipitoposterior Position with Report of 1,392 Collected Cases."

GENERAL

Infantile Paralysis Fund Aids Soldiers' and Sailors' Dependents.—Chapters of the National Foundation for Infantile Paralysis will put the money received by them this year from the President's Birthday Celebration to a new use. In accordance with an agreement between President Roosevelt and the national foundation a part of the funds received by the chapters will be used wherever necessary to assist the dependents of any man in the military or naval service of the United States who becomes a victim of infantile paralysis while in the service. The foundation will issue regulations authorizing this expanded defense activity of the chapters.

American Orthopsychiatric Association.—The nineteenth annual meeting of the American Orthopsychiatric Association will be held at the Hotel Statler, Detroit, February 19-21. One general session will be devoted to "Research in Child and Youth as Defense Effort." There will be round table discussions on "Orthopsychiatry and the National Defense," "College Mental Hygiene," "The Provision of Psychiatric Services to Rural Areas," "Psychoanalytic Orientation in Family Casework" and "Present Day Trends in the Functions of the Clinical Psychologist." A special section meeting will be held on "Orthopsychiatry and the Profession of Education."

Special Society Elections.—Dr. Willis D. Gatch, Indianapolis, was elected president of the Western Surgical Association at its recent annual meeting in St. Paul. Other officers included Drs. Elmer M. Jones, St. Paul, and E. Eric Larson, Los Angeles, vice presidents; Arthur R. Metz, Chicago, secretary, and Verne C. Hunt, Los Angeles, treasurer. The next annual meeting will be held in Memphis in December. The American Society of Anesthetists chose the following officers among others at its annual meeting December 11: Drs. Wesley Bourne, Westmount, Que., Canada, president; Frederick A. D. Alexander, Albany, N. Y., Urban H. Eversole, Boston, Hubert R. Hathaway, San Francisco, vice presidents, and Paul M. Wood, New York, secretary.

Schering Corporation Officials Suspended.—As a step toward "smashing completely a long range German scheme to control an important segment of the pharmaceutical market in the western hemisphere," the U. S. Treasury announced on January 29 that it had suspended President Julius Weltzien and seven other officials of the Schering corporation of Bloomfield, N. J., manufacturers of various medicines essential to the war effort, the Chicago Daily Tribune reported. Schering corporation is a subsidiary of Schering A. G. of Berlin, Germany. Production has been under treasury supervision since the Japanese attack on Pearl Harbor, the Tribune stated. The eight company officials were barred from the Schering premises, their personal accounts were blocked, and employees of the company were forbidden to communicate with them.

Examinations in Obstetrics and Gynecology.—The American Board of Obstetrics and Gynecology announces that the general oral and pathologic examinations (part 2) for all candidates (groups A and B) will be conducted at Atlantic City, N. J., by the entire board from Wednesday June 3

through Tuesday June 9, 1942 prior to the opening of the annual meeting of the American Medical Association. Application for admission to group A, part 2, examinations must be on file in the secretary's office not later than March 1. It will greatly facilitate the work of the board if applications are filed as far as possible in advance of the closing date for their receipt. Formal notice of the time and place of these examinations will be sent each candidate several weeks in advance of the examination dates. Candidates for reexamination in part 2 must make written application to the secretary's office before April 15. Dr. Paul Titus is secretary of the board, 1015 Highland Building, Pittsburgh.

Certification of Proctologists.—The National Proctologic Certification Committee has been established under the sponsorship of the Section on Gastro-Enterology and Proctology of the American Medical Association, the Section on Proctology of the Southern Medical Association, the American Proctologic Society and the Mid-West Proctologic Society. Representatives from each group will serve overlapping four year terms on the committee, which is currently made up of Drs. Louis J. Hirschman, Detroit, chairman; Walter A. Fansler, Minneapolis, vice chairman; Louis A. Buie, Rochester, Minn.; Edward G. Martin, Detroit; Descum C. McKenney, Buffalo; Marion C. Pruitt, Atlanta, Ga.; Frank G. Runyeon, Reading, Pa.; Frank C. Yeomans, New York, and Curtice Rosser, Dallas, Texas, secretary. The new committee will cooperate with the American Board of Surgery in passing on the qualifications of applicants who desire certification in proctology and will have charge of that portion of the examination of these applicants covering the diseases and surgery of the colon, rectum and anus. A Founders' Group has been instituted, composed primarily of those who have practiced proctology for fifteen years or who are professors or assistant professors of proctology. The preliminary group was nominated by the original American Board of Proctology, which was responsible for the creation of the new certification committee and was subject to a veto of the American Board of Surgery. Additions to this group will be made until Jan. 1, 1944. Additional information may be obtained from Dr. John Stewart Rodman, secretary of the American Board of Surgery, 225 West Fifteenth Street, Philadelphia.

Annual Report of Commonwealth Fund.—The Commonwealth Fund reported January 19 that it had expended \$1,841,332.46 in the year ended Sept. 30, 1941 for purposes associated with the "welfare of mankind." Of this total more than \$262,000 was appropriated for public health activities in Oklahoma, Tennessee, Mississippi, Alabama and Massachusetts. Mental hygiene activities in the United States and England received \$156,820. Special grants totaling \$366,712 went to medical research projects in various universities, medical schools and hospitals, the largest appropriation of \$111,177 going to a study of arthritis at Harvard Medical School, and the second largest, \$42,000, to research in the function of the kidney at the University of Pennsylvania School of Medicine, Philadelphia. This project has been suspended because Dr. Alfred Newton Richards and his principal research associate, Dr. Arthur M. Walker, have been called to serve with the Committee on Medical Research in the Office of Scientific Research and Development. Other subjects covered by the fund's miscellaneous grants included air borne infection, bacterial nutritive requirements, chemical factors involved in resistance to disease, relation of endocrines to growth and development, mechanism of heart failure, immunology, influenza bacillus, chronic nephritis, peripheral circulation, pneumonia, poliomyelitis, respiratory physiology, rheumatic fever, the streptococcus, the vaginal smear as a diagnostic method and the etiology of vascular disease.

The fund gave support in twenty-eight states and in Great Britain. Of thirty-eight separate projects aided by the fund only three were new, two in New York and one in Chicago. In New York these were a clinical statistical review of a series of cases of essential hypertension at the Columbia-Presbyterian Medical Center and a study of gynecologic diagnostic methods at Cornell University Medical School. The Chicago project is a study of cancer producing substances from human tissues at the University of Chicago. At five schools of medicine the fund subsidized departments of preventive medicine, and special provision was made for the expansion of this department at Tulane University of Louisiana School of Medicine, New Orleans. The department of psychiatry at the University of Louisville was subsidized, and at four medical schools the fund helped to meet the cost of borderline services designed to link the departments of psychiatry and pediatrics. A grant was made to the Peter Bent Brigham Hospital in Boston to enlarge a psychiatric service forming part of the department of medicine. No new hospital award was made.

during the year, but a community hospital at Pittsfield, Ill., was completed and one at Mount Pleasant, Mich., was begun. The capacity of a hospital at Kingsport, Tenn., was doubled, the cost being divided between the fund and the community. The twelve hospitals already in service under this program were used almost to normal working capacity, and their earned income rose faster than their operating expenses, according to the report.

Since the war began the fund has set aside \$685,000 for war relief and related activities. Direct gifts have been made to the British War Relief Society, the United China Relief, the Greek War Relief Association, the American Field Service, the American Friends Service Committee, the United Service Organizations and the American Red Cross. It has contributed to the Harvard-Red Cross Epidemiological Unit, now operating a hospital and field service for communicable disease control in England, and to the American Hospital in Britain.

CANADA

New Division of Nutrition.—The Department of Pensions and National Health of Canada has established a division of nutrition with Lionel B. Pett, Ph.D., Edmonton, Alta., as director. Miss Marion Harlow, Montreal, is assistant director. According to the *Canadian Public Health Journal* the new division has a limited budget and it will be necessary to secure the cooperation of all existing agencies to undertake a national program of nutrition education.

Graduate Course in Therapeutics.—A postgraduate course in therapeutics will be held by the University of Manitoba Faculty of Medicine, Winnipeg, February 11-13. Guest speakers will be Drs. Cecil J. Watson, professor of internal medicine, University of Minnesota Medical School, Minneapolis, and William F. Gillespie, professor of surgery, University of Alberta Faculty of Medicine, Edmonton. On February 13 Dr. Gillespie will address a meeting of the Winnipeg Medical Society on "Physiological Principles in the Repair of Inguinal Hernia," and Dr. Watson, "Some Physiological and Clinical Aspects of Jaundice."

LATIN AMERICA

Scientific Conference in Mexico.—An Inter-American Scientific Conference will be held in Mexico, February 15-26, as a part of the dedication of the new National Astrophysical Observatory. Most of the sessions and lectures will be held at Puebla, including the dedicatory exercises on the morning of February 17. Dedicatory addresses will be given by President Manuel Avila Camacho and the governor of Puebla. For special academic ceremonies an excursion will be made to Morelia on February 23 and 24, with the final sessions being held in Mexico City. The new observatory is situated on land provided by the government of the state of Puebla, near a small town of Aztec origin called Tonanzintla, about 80 miles east of Mexico City.

Argentine Clinic to Be Center for Cyclotron Products.—The Instituto de Radiologia de Fisioterapia Medica del Hospital de Clinicas in Buenos Aires, Argentina, will be the permanently established center at which treatment with the cyclotron products may be had in South America, according to the University of California *Clip Sheet*. The first shipment of radioactive phosphorus has been sent to the institute by the University of California Radiation Laboratory, Berkeley, and it is intended to send a shipment of 10 millicuries by Pan American Airways every two weeks. Previously a few shipments were sent to Lima, Peru, but these were not regular, the *Clip Sheet* stated. Radioactive phosphorus retains its radium-like qualities for fourteen days, after which it is not active enough to be useful. The shipments arrive in Buenos Aires in about two or three days and are thus useful for more than ten days. The cyclotron product has been found beneficial in the treatment of leukemia.

CORRECTIONS

Finlay Institute of the Americas.—In the current comment on the Finlay Institute of the Americas in *THE JOURNAL*, January 17, page 230, the name of Morton Kahn, a member of the Scientific Advisory Committee, was inadvertently omitted.

Alwin Pappenheimer Jr. Receives Lilly Award.—*THE JOURNAL*, January 24, page 310, reported that the Eli Lilly Award of \$1,000 and a bronze medal, presented during the meeting of the Society of American Bacteriologists in Baltimore, December 30, had been given Dr. Alwin M. Pappenheimer, professor of pathology, Columbia University College of Physicians and Surgeons. *THE JOURNAL* should have reported

that this award is given to a scientist under 35 years of age. This year it went to Alwin M. Pappenheimer Jr., Ph.D., assistant professor of bacteriology, New York University College of Medicine, New York, for his work in developing a new science combining bacteriology, chemistry, physics and nutrition in the treatment of disease.

Government Services

Positions Open Soon in Panama Canal Service

The U. S. Civil Service Commission expects to begin accepting applications on February 16 for physician positions in the Panama Canal Service. The formal announcement which will be issued on that date will give details as to the training, age, physical and other requirements. Copies will be obtainable, with the application forms, at any first or second class post office, or by writing to the Civil Service Commission, Washington, D. C., after February 16. These positions pay about \$4,000 a year. The duties are described as follows:

To serve as district physician in a small government dispensary; as such to have general supervision over all medical and surgical activities in the dispensary; to operate a general medical and surgical clinic, to examine and vaccinate school children; to examine new employees of the Panama Canal to determine their fitness for entering the service; to attend emergency injury cases; to visit patients day or night; to diagnose cases and treat patients in their homes and on board ships, and to be in charge of business activities of dispensary such as ordering of supplies, care and upkeep of buildings and equipment, and accountability for property and cash.

Doctors are urged to keep this notice in mind and apply for further details after February 16.

Examination for Appointment in Public Health Service

The U. S. Public Health Service announces an examination to establish eligibility for appointment in the commissioned corps of the service in the grade of assistant surgeon (medical only). Applicants must not have passed their thirty-second birthday on the date the examination is taken, must be citizens of the United States, must be graduates of an approved medical college and must have completed or will complete by July 1 next at least one year of internship or its equivalent. The compensation of officers in the grade of assistant surgeon, both Regular and Reserve Corps, is \$3,158 a year with dependents and \$2,699 a year without dependents.

The board of examiners will be in the following places at 9 a. m. on the dates specified. Candidates should arrange to have their physical examinations completed and prepare their autobiographies at any one of the following listed places just prior to the date shown:

U. S. Marine Hospital, Boston	February 9
U. S. Marine Hospital, Staten Island, N. Y.	February 10
U. S. Marine Hospital, Baltimore	February 12
U. S. Marine Hospital, Norfolk, Va.	February 13
U. S. Marine Hospital, Cleveland	February 16
U. S. Marine Hospital, Louisville, Ky.	February 17
U. S. Public Health Service, Washington, D. C.	February 20
U. S. Marine Hospital, Chicago	February 23
218 Federal Office Building, Minneapolis	February 24
U. S. Marine Hospital, Seattle	March 2
U. S. Marine Hospital, San Francisco	March 6
U. S. P. H. S. Relief Station, 424 Federal Bldg., Los Angeles	March 9
Colorado Psychopathic Hospital, Denver	March 11
U. S. Marine Hospital, Kirkwood, Mo.	March 13
U. S. P. H. S. Hospital, Fort Worth, Texas	March 27
U. S. Marine Hospital, New Orleans	March 30
Liaison Office, U. S. P. H. S., Room 319 Grant Bldg., Atlanta, Ga.	March 31

Those persons who complete the physical examination and certain other portions of the examination consuming from one to three days will be permitted to participate later in the written examination beginning on April 7, either at the place where the physical examination was conducted or at some other nearer point. The written and clinical portions of the examination will consume about five days. Any travel expenses to be incurred must be defrayed by the applicants. Applicants may obtain application blanks by writing to the Surgeon General, U. S. Public Health Service, Washington, D. C. These forms may be filled out and delivered personally to the board of examiners, or blanks may be had from the board at the time the applicant appears for examination. Applicants will be required to present their diplomas and evidence of United States citizenship, to the board. If naturalized, naturalization certificate should be presented to the board. Candidates born in the United States who pass the entire examination will be required to prove citizenship before being offered appointment. National Board diplomates are required to present their certificates to the board.

The British Population Problem

All over the world today there is a population problem. In the more backward countries the birth rate is too high for general prosperity, while in the more advanced countries it is not high enough to maintain the population. In an address to the Devonshire club the duke of Devonshire, undersecretary of state for India, took for his subject "Empire." One of the difficulties arising from the war was the populating of the empire. The day must come, and in the not very distant future, when, in spite of the considerable increase in the duration of life, the British population would begin to shrink rapidly. We needed a birth rate of 19.5 per thousand but had at present one of only 16. The dominions were also faced with the problem of a diminishing population in the near future. When they had a vastly larger population the peace of the world would be secure. He suggested that the dominion governments might investigate the possibility of increasing their populations by admitting the peoples of northern countries, such as Denmark, Sweden and Norway, who to a large extent shared our views and were of the same blood.

War Nurseries

A feature in this war, as of the last, is the extensive use of female labor both directly in the war effort, as in munition work and in auxiliary services to the fighting forces, and indirectly in releasing men by performing work which in peace time is done solely by them, such as that of bus and street car conductors and railway porters. At present there is an urgent call for more women in the war industries, particularly for strong young women with recent industrial experience. But many such women are mothers of young children and cannot be expected to do work efficiently, or even at all, unless assured that their children are being well cared for during their absence from home. Not unmindful of this, the Ministry of Labor has established nurseries for the children of war workers. In June last this provision was expanded; the government took full financial responsibility for the nurseries, which were opened to the children of all women in full time employment. Their administration was placed in the hands of a joint staff of the Ministry of Health and the Board of Education, the local authority responsible being the Maternity and Child Welfare Authority. The difficulty of establishing these nurseries in the numbers they are required is now pressing.

Concession to Alien Physicians

Mainly to meet the case of Jewish physicians, who were penalized by the Germans, a new defense regulation has been made which provides that a foreign physician who has passed the necessary examinations for a foreign diploma but was debarred from practice in his own country by racial legislation may be given temporary registration in Britain. Before this it was necessary for a foreign physician to hold a diploma before he could be registered and so become legally entitled to practice. Another change is that an alien or oversea physician who fulfils the other prescribed conditions may now be employed in private practice as an assistant to a physician on the permanent register. Any physician who does not possess any United Kingdom qualification may be registered for the period of the war if he satisfies the General Medical Council that he is of good character, holds a medical diploma recognized as sufficient by the council and has been selected for employment as a medi-

cal officer in an approved hospital, institution or service, or as assistant to a physician on the permanent register.

Apart from American physicians, who are dealt with under a special order, four hundred and seventy alien physicians are employed in the service of this country. Of these three hundred and eighty-five are employed in hospitals, thirty-three in public health appointments and fifty-two as ship surgeons or in other miscellaneous posts. In addition twenty-four have received commissions in our fighting forces, apart from those serving in the allied forces.

The Food Problem

The food provided in the different departments of France is unequal, although there is a uniform ration card. Some not rationed foods are still to be found in some departments. The supply, however, has diminished, and on account of the war these districts do not have enough food for their own requirements. On the other hand, the providing of food for the cities is aggravated by transport difficulties due to the shortage of coal and gasoline. On the whole, people living in the open country are better provided for than are the people in the cities, just as it was in the the last war. The government of Vichy is trying to organize the distribution of food by means of special commissions and is endeavoring to accumulate stocks for the coming winter. Price regulation for all products has been adopted.

THE RATION CARD FOR OCTOBER AND NOVEMBER

In October and November the following rations were granted: 275 Gm. (9 ounces) of bread a day for an adult. A weekly meat ration with bones ought to have amounted to 250 Gm. (8¾ ounces) but actually amounted to only 100 to 200 Gm. (3½ to 7 ounces). The sugar ration was 125 Gm. (4 ounces) a week, the cheese ration 55 Gm. (nearly 2 ounces), the fat ration 110 Gm. (3⅗ ounces), which means 55 Gm. less than in September. This fat ration included only 25 Gm. (⅞ ounce) of butter for the whole month. Sixty Gm. (2 ounces) of nutritious paste a week were granted and 1 Kg. (2¼ pounds) of potatoes. The coffee ration amounted to 60 Gm. a month.

Laborers got a bread supplement of 75 Gm. (2½ ounces) a day, a weekly meat supplement of 100 to 225 Gm. (3½ to 8 ounces) and a fat supplement of 75 to 150 Gm. (2½ to 5 ounces) a week.

The daily bread ration for children up to 3 years of age is 100 Gm. (3½ ounces), for children between 3 and 6 years 200 Gm. (7 ounces), between 6 and 13 years 275 Gm. (9½ ounces) and between 13 and 21 years 350 Gm. (12 ounces). Children up to 3 years of age get 50 Gm. (1½ ounces) of rice a week and a sugar ration of 250 Gm. (8¾ ounces) instead of 125 Gm. (4 ounces) a week. The daily milk ration amounts to 0.5 liter (1 pint) for children between 3 and 7 years and 0.25 liter (½ pint) for children between 7 and 14 years of age. Besides, children up to 6 years are getting 125 Gm. (one-fourth pound) of chocolate a month, children and young people between 6 and 21 years 250 Gm. (one-half pound). Children and adolescents up to 21 do not get any coffee.

Inquiries into the physiologic value of this feeding have been made in comparison with the minimum necessary for the organism. Of importance is the research work of Mrs. Randoïn, an authority on the physiology of nutrition and director of the Laboratoire de Physiologie de la nutrition at the Ecole des hautes études and of the Institut supérieur de l'alimentation. This work was done by means of exact laboratory experiments as to the value and the composition of different elements and with many inquiries carried on in the various districts of France. These institutes endeavor to do scientific research work and

also to solve purely practical problems regarding the substances indispensable for the body in order to supply them in the inadequate diet. The results of these inquiries have been discussed in meetings at the Académie de médecine, which has created a special Commission du rationnement alimentaire to study these problems thoroughly.

THE PHYSIOLOGIC VALUE OF THE FOOD RATION

The ration, which has remained stationary for a year in spite of slight alterations, has proved insufficient. The ration grants 1,225 calories a day, about half of the normal requirement of calories the average active person ought to have. Everybody must try to supply additional calories by providing himself with other food from the not rationed food market. In the daily ration are 220 Gm. of carbohydrate instead of the norm of 450 Gm. and 12 Gm. of animal albumin instead of the minimum of 30 Gm. That is why the ration does not contain a large part of the indispensable amino acids: leucine, isoleucine, phenylalanine, tryptophan, lysine and histidine, substances that the body cannot itself produce. These amino acids exist in the right ratio in animal and not in vegetable proteins; in the ration their proportion to one another is to the disadvantage of the animal proteins. Twenty-one Gm. of lipids of animal and vegetable origin is contained in the daily food ration, which is only about half of the strictly necessary daily minimum of 40 Gm. A great deal of the indispensable fatty acids is missing in the ration, for instance linoleic and linolenic acid, as well as a certain amount of vitamin E, which is derived from vegetable fats. At the same time much of the oil soluble vitamins A and D is missing, as well as a further amount of the vitamin E that animal lipids include, especially butter and other milk derivatives. Only a small quantity of them are contained in the ration. This feeding causes, on the other hand, an acid surplus in the body on account of the preponderance of acid residues over base residues.

CALCIUM DEFICIENCY IN THE DIET

At a meeting of the Académie de médecine Mrs. Randoin and Mr. Richet recently discussed calcium deficiency in the feeding of young people. A calcium shortage was found present before the war by means of research done by Mrs. Randoin in 1937 and 1938. In the meantime the deficiency has been increasing as the result of inadequate feeding.

Calcium Requirement and Deficiency

Age	Strictly Necessary Minimum of Calcium, Mg.	Supplied by Normal Food, Mg.	Contained in the Actual Food Ration, Mg.	Deficit, per Cent
5.....	210	693	1,044	..
6.....	217	716	444	38
8.....	277	914	444	51
10.....	276	910	444	51
12.....	335	1,105	444	60
14.....	410	1,350	141	89
16.....	550	1,675	141	92
20.....	450	1,485	141	90
30.....	450	1,485	141	90
Pregnant woman...	900	2,970	793	73.2

The rationed food is extremely poor in all minerals and especially in calcium. Two thirds of the necessary phosphorus, two thirds of the magnesium, three fourths of potassium and six sevenths of calcium are missing in the food of young people. The ration is supplying only 0.18 Gm. of calcium a day instead of 1.30 Gm., which an adolescent ought to get in his food. The phosphorus amounts to 0.52 Gm. a day instead of 1.45 Gm. The proportion of calcium to phosphorus amounts to 0.34 instead of the normal ratio of 0.9. The calcium phosphorus ratio for adults has also been displaced from the normal.

In their remarkable book *Carence calcique et régime alimentaire* (Calcium Deficiency and Alimentary Regimen), published this year, H. and M. Hinglais, directors of the laboratory at the Faculté de médecine, give figures comparing the calcium requirement of the organism, its amount in a well balanced ration and that in the actual food ration.

It has been stated that calcium taken in any form is assimilated by the body in the ratio of 50 per cent during the first

Vitamin D

Age	Strictly Necessary Minimum, International Units	Supplied by the Actual Food	Deficit, per Cent
1.....	400	25	93.7
5.....	400	25	93.7
6.....	400	7	98.2
13.....	400	7	98.2
14.....	400	9	97.7
18.....	400	9	95.5
30.....	200	9	97
Pregnant woman.....	800	24	97

year and 25 to 30 per cent at all other ages. This table shows that the actual food ration offers a sufficient amount of calcium only up to the age of 6 years.

To activate the calcium, a sufficient amount of vitamin D is needed. The authors give instructive figures comparing the vitamin D requirement of the body and its supply in actual food.

Children up to the age of 6, who alone have enough calcium in the actual food, are getting the same amount of vitamin D as the other ages, only in an extremely inconsiderable amount; as a result the sufficient amount of calcium cannot be assimilated in the body. The consequences of these deficiencies have already been observed. In the Société médicale des Hôpitaux de Paris Mrs. Pierre Bourgeois reports that tuberculosis among children is increasing. Mrs. Randoin proposed at a meeting of the Académie de médecine the medicinal administration of calcium in the best assimilable form of an organic salt in a daily dosage of 1 Gm. as well as the administration of the amount of vitamin D necessary for its assimilation. This proposal was approved by the Académie.

VITAMINS IN THE RATION

The actual food ration is extremely poor in vitamins. As Mrs. Randoin states, the ration contains only one third to one fourth of the amount included in normal feeding, and several diseases due to vitamin deficiency have already been observed. Polonowski reports cases of hemeralopia caused by the lack of vitamin A. At a meeting of the Société de pédiatrie Clement mentioned several cases of xerophthalmia among nurslings, also due to a vitamin A shortage. In the Société médico-psychologique, Sivadon and others referred to mass phenomena of diseases resembling beriberi among the insane due to vitamin B₁ deficiency. Cases of scurvy have also been observed. At the Société des médecins du nord, Demorez and Boulanger reported postoperative hemorrhages and hemorrhages of the gums due to vitamin C deficiency. Of utmost interest are the reports of Raoul Lecoq in the Académie de médecine on polyneuritic symptoms, which were first supposed to be an avitaminosis and proved later to be caused by an acidosis due to inadequate feeding in general. Professor Mouriquand calls these cases of vitamin deficiency reversible, and they can be cured by medical treatment. The symptoms of the so-called paravitaminosis producing irreversible changes are to be expected only after a prolonged lack of vitamins.

The Section d'alimentation of the Comité consultatif d'hygiène at Vichy determined to organize the systematic distribution of vitamins A, B and C. Professor Lesne, a specialist in vitamin research, believes that the effect of natural vitamins is superior

to that of the artificial ones. For instance, the treatment of scurvy by giving 50 cc. of lemon juice containing 25 mg. of ascorbic acid produces quicker results than 25 mg. of ascorbic acid administered as a medicament. The artificial vitamins, especially vitamin C, are quickly absorbed and also quickly secreted by the kidney. These vitamins have to be administered every day in order to be efficacious. Besides, there exists an antagonism among the different artificial vitamins. The body eliminates, for instance, vitamin C if vitamin A or D is administered simultaneously. Professor Lesne said at a meeting of the Académie de médecine that if good results have been realized with the administration of artificial vitamins "they are not able to mend the deficiency due to inadequate food."

MEXICO CITY

(From Our Regular Correspondent)

Jan. 21, 1942.

Population Problems in Mexico

The Bureau of Statistics and Economical Studies of the Central Department in the Federal District has collected the following data: According to the census of March 6, 1940 the Federal District, including Mexico City, has a population of 1,749,916 inhabitants, twice the figure given in the 1921 census and 37.8 per cent higher than in 1930, the result, undoubtedly, of immigration from the rural zones, especially the southern states. Mexico City in population has the seventeenth place in the world and the seventh on the American continent. The mean population in the city of Mexico is 10,951 inhabitants per square kilometer. The northeastern quarters have a human density of 27,927 per square kilometer and in towns and villages surrounding the city, which form the Federal District, the mean population is only 233 inhabitants per square kilometer. This zone contains 366,006 families with an average of 4.8 members per family, against 5.16 shown in the census of 1930. During the last decade 1,478,405 children were born in the Federal District and only 971,800 were alive on the day of the census, which means that one child out of three dies before reaching boyhood. The highest infant and child mortality is registered among the people living in the poorest quarters of the city or else in the suburbs in which sanitation is faulty. In the Federal District 98 per cent of the inhabitants speak Spanish, 6 per cent speak other languages besides and only 2 per cent do not speak Spanish but foreign languages. Only about 4 per cent live in houses of their own. All wear shoes with the exception of some natives and foreigners, who wear "huaraches" (sandals). Marriages increased, but divorces were three times what they were ten years ago.

Malaria in Mexico

For a long time, malaria has been one of the greatest public health problems in Mexico, principally in the tropical rural zones and along the coasts. Few special studies have been carried on to determine its prevalence, the mass immunity and resistance of individuals and the bionomics of the species of anophelids present in the different malarial areas. The annual mortality rates for the three principal causes of death for 1922 and 1938 in Mexico were:

	Average Number of Deaths		Rate per 100,000	
	1922	1938	1922	1938
Diarrheas and enteritis.	25,765	82,772	178.37	424.93
Pneumonias.....	53,744	62,376	235.61	320.23
Malaria.....	25,035	21,760	173.21	127.11

No reliable figures are available regarding morbidity, although malaria is one of the heaviest burdens supported by the Mexican people. The Bureau of Biostatistics of the Federal Department of Health states that there are more than 5 million patients

every year. According to the economic capacity of the country and pursuant to the ordinance of Aug. 29, 1938 the Federal Department of Health has been working on a program based on three fundamental points: sanitation, education of the public and curative and preventive treatment of those living in heavily infested areas, besides other secondary measures. In accordance with the program, the sanitation of Acapulco Harbor, one of the most popular summer resorts in Mexico, the city and port of Mazatlán, Manzanillo Harbor on the Pacific Coast as well as some other cities, such as Guadalajara, in the rural zones in the South and Atlantic Coast, have been carried on successfully during last year. The planting of cinchona trees by the Federal Department of Health will be increased in special places chosen for that purpose in the state of Chiapas in the southwestern part of Mexico, in which twenty-four thousand cinchona trees have been planted, besides more planted in a zone of the state of Tamaulipas, by the department of agriculture. The free distribution of antimalarial medicines will continue and a new laboratory specially dedicated to the study of malaria in Huixtla, Chiapas, located in the heart of the tropical region, will be inaugurated this year. In the annual budget for 1942, besides the amount to be collected from the mosquito stamp, nearly a million pesos (about \$200,000) will be spent in sanitation of rural areas.

Registration and Certification of Drugs, Foods and Cosmetics

The official organ of the House of Representatives publishes the new amendments to the Food, Drugs and Cosmetics Act related to the requisites for registration, taxes and duties for certification of such products. According to the new enactments, a patent medicine is any drug, medicine or pharmaceutical formula with a special name or trademark consistent with the patent law. Patent food is any food or beverage with a trademark. In general the registration rules consider as a food "anything introduced in the digestive tract without therapeutic purpose." A cosmetic is any perfume, face powder, cream, paste or the like, including medical soaps, destined to the beautifying of a person. According to article 6 the new registration taxes for drugs and cosmetics with foreign trademarks are 200 pesos, for drugs and cosmetics with domestic trademarks 20 pesos, for foods with foreign trademarks 50 pesos and for foods with domestic trademarks 20 pesos (the peso is equivalent to about 20 cents). Besides these registration taxes, all units or pieces of a patent medicine, drug, food or cosmetic should be certified by a stamp adhered to it and according to article 12 only a product accepted by the Food and Drug Committee of the Federal Department of Health can bear such a stamp and be put on sale. An official list of accepted products will be published periodically, and all products on sale without fulfilling all requirements will be confiscated and the firms will be fined.

The Fifth National Dental Congress

The fifth National Dental Congress organized by the Mexican Dental Federation affiliated with the International Federation of Dentists was inaugurated by Dr. Victor Fernández Manero, chief of the Federal Department of Health, on January 12 at the general session held at the Beaux Arts Palace in Mexico City. At the speakers' table, besides Dr. Fernández Manero, who represented the president of the Republic, were Dr. E. G. Loogan, president of the International Dental Federation, Dr. Gustavo Baz, secretary of public welfare, Dr. José J. Rojo, president of the Mexican Dental Federation, Dr. P. Ventruela from Guatemala and other representatives from Central and South American countries. Dr. Gustavo Baz, secretary of public welfare, announced that in accordance with President Camacho's orders the National Dental Institute will be established during the present year. The congress, which was organized under the auspices of the National University, the Federal Department of Health and the Federal District Central Depart-

ment had a twofold purpose: to aid the progress of dentistry and strengthen the relationship between dentists in American countries. The transactions during the week consisted of scientific reports, papers and demonstrations, information to the public regarding dental and oral hygiene and exhibitions both commercial and scientific. All sessions were held at the National School of Dentistry. Three important reports were presented, on dentistry in relation to general diseases, dental ethics and modern trends in some dental problems. The closing general session was held on Saturday evening January 10. The officers of the old governing council were reelected for the new term.

AUSTRALIA

(From Our Regular Correspondent)

Nov. 15, 1941.

Social Security Revived in Australia

Following the defeat of the national government in Australia and the subsequent formation of a labor ministry, the question of social security and health insurance has again been brought up. Australia's new prime minister (Mr. Curtin) has stated that the newly formed labor government does not intend to overlook the fact that the establishment of a health insurance scheme has always been one of its major objectives. Meanwhile a general medical service for all Australians whose income does not exceed £416 a year has been approved as a policy by the federal council of the British Medical Association.

The plan presupposes the establishment of a national health insurance scheme to be administered by a statutory board of management. Main principles of the scheme are:

1. The system of medical service to be directed to the achievement of positive health and prevention of disease as much as to the relief of sickness.
2. Provision of the services of a general practitioner or a family doctor of his own choice for every individual.
3. Consultant, specialist, laboratory and all necessary auxiliary services with institutional provision when required to be available for the individual patient. Normally this would be done through the family doctor.
4. The several parts of the complete medical services to be closely coordinated and developed by applying a planned national health policy.

The plan was adopted at a recent meeting of the council.

Wireless Transmitting Apparatus (Possession) Order

To avoid the possibility of diathermy and other high frequency electrical apparatus causing interference to defense and other essential radio services, and to minimize the possibility of such apparatus being put to improper use, an order has been made under the national security regulations, which requires that no person, association, company, hospital, clinic or institution shall possess or operate the following types of apparatus without a license, if such apparatus develops power exceeding 10 watts at frequency exceeding 10,000 cycles per second: (a) Diathermy or other electromedical apparatus in which valves or spark coils are used, not including normal modern types of violet ray, ultraviolet ray, infra-red ray or x-ray apparatus or medical shocking coils. (b) High frequency furnaces. (c) Eddy current heating apparatus. (d) High frequency testing oscillators.

Before a license to operate any of this equipment is issued, the apparatus, or the room or premises in which the apparatus is installed, must be screened or otherwise treated so that interference will not be caused to authorized radio services. In the United Kingdom the equivalent regulation forbids absolutely the possession of diathermy apparatus by any private individual and even by private hospitals and clinics, but the Australian authorities consider that the situation does not warrant such sweeping action in the commonwealth.

War and the Activities of the Council for Scientific and Industrial Research

On the outbreak of war the Council for Scientific and Industrial Research considered the steps which could be taken to reorientate its investigations so as to render assistance in as direct a way as possible to the war effort of the British commonwealth of nations. It was not easy to make an immediate change over, but as the national effort gained momentum it was possible to devote more attention to studies directly related to war requirements. These studies have covered questions such as what Australian materials can replace materials previously imported, how best Australian materials can be used in new industries, what can be done to reduce the difficulties caused by any particular damming up of Australian exports and what can be done to alleviate difficulties caused by the upset of normal conditions. The division of food preservation and transport is working on the drying of various foodstuffs with a view to the export in that condition and a consequent saving of freight space. Particular attention is being given to eggs. The fisheries division is giving attention to the production of fish oils rich in vitamins and needed to replace cod liver oil, which it is no longer possible to obtain from Europe. Potash (for the dipping of dried vine fruits) is now difficult to obtain, but it has been shown that the shortage can be overcome by extracting potash from vine prunings. The division of plant industry is investigating the production of medicinal plants. At the request of the medical equipment control committee an investigation has been undertaken of the problem of growing certain essential drug plants. The chief plants concerned are *Atropa belladonna*, *Artemisia maritima*, *Cephaelis ipecacuanha*, *Claviceps purpurea*, *Cinchona*, *Datura*, *Duboisia*, *Digitalis*, *Dryopteris Filix-mas*, *Ephedra*, *Papaver somniferum* and *Strychnos nux-vomica*.

Australian-American Association

The movement toward forming the Australian-American Association was initiated by a body of Australian citizens in the belief that the ideals and outlook on life of the peoples of America and Australia are so closely allied that it needs only a thorough knowledge of each other to achieve mutual respect and full understanding of each other's point of view; that the future peace, freedom and prosperity of the Pacific largely depend on the achievement of such an understanding and friendly regard between these two peoples, and that the close friendship of the vigorous democracies of the New World may well be the decisive factor in reestablishing the principles of freedom in a threatened civilization.

The Australian-American Association has as its objects (1) to extend fellowship and hospitality to American visitors to our shores and to afford them facilities for obtaining an immediate knowledge of Australia, (2) to contribute to a better understanding by the Australian public of American affairs and point of view and (3) to attract in active membership citizens of both countries who will contribute to the furtherance of practical cooperation and mutual understanding.

Marriages

EDWARD BALDWIN SELF, South Orange, N. J., to Miss Beatrice Marie Bellinger of Woodside, L. I., N. Y., Nov. 6, 1941.

WILBUR FISKE LEIGHTON, Portland, Maine, to Miss Wilhelmina Gerard Herrmann of Jersey City, N. J., Oct. 31, 1941.

RICHARD DUPUY NIERLING, Jamestown, N. D., to Miss Grace Jessie Erickson at Grand Forks, Dec. 27, 1941.

FUNSTON J. ECKDALL, Emporia, Kan., to Miss Clara R. Maury of Schenectady, N. Y., Dec. 10, 1941.

PAUL H. BRAUER to Miss Arlette Philippous, both of New York, June 14, 1941.

Deaths

Soma Weiss ☉ Boston; Hersey professor of theory and practice of physic at the Harvard Medical School and the graduate school, died, January 31, aged 43. Dr. Weiss was born in Besterce, Hungary, Jan. 27, 1899. He received an A.B. from Columbia University, New York, in 1921 and graduated from Cornell University Medical College, New York, in 1923. He served as demonstrator and research fellow in physiology and biochemistry at the Royal Hungarian University in Budapest between 1917 and 1920, when he became assistant in pharmacology at Cornell and served in that capacity until 1923. He joined the faculty of Harvard Medical School in 1925 as assistant in medicine, was instructor in medicine from 1927 to 1929, assistant professor from 1929 to 1932 and associate professor from 1932 to 1939. Dr. Weiss was a member of the American Society for Clinical Investigation, the American Academy of Arts and Sciences, the American Heart Association and the Association of American Physicians and numerous others and fellow of the American College of Physicians. He was the second to hold the post of physician in chief of the Peter Bent Brigham Hospital. He was formerly associate physician and assistant director of the Thorndike Memorial Laboratory of the Boston City Hospital, director of the Second and Fourth Harvard Medical Services at the City Hospital and later chief of the Fourth Service. Dr. Weiss was a member of the Council on Pharmacy and Chemistry of the American Medical Association and a member of the United States Pharmacopeial Revision Committee. He was especially well known for his work on cardiovascular disease.

Charles Hatch Stoddard, Milwaukee; College of Physicians and Surgeons of Chicago, 1892; member of the House of Delegates of the American Medical Association in 1916; member of the board of directors of the Wisconsin Anti-Tuberculosis Association from 1909 to 1911, vice president from 1925 to 1930, president, 1931-1932, and recording secretary from 1933 to 1941; in 1918 and in 1932 vice president of the Milwaukee Academy of Medicine; member of the first Wisconsin committee of the International Congress on Tuberculosis in 1908; in 1927 president of the Milwaukee County Medical Society; fellow of the American College of Physicians; was a major in the medical corps of the Wisconsin National Guard during the World War; in 1907 first medical director and superintendent of the Bluemond Sanatorium; on the staffs of the Columbia Hospital, Mount Sinai Hospital, St. Mary's Hospital, Milwaukee County Hospital and the Milwaukee Hospital; aged 72; died, Dec. 17, 1941, of chronic nephritis.

George Albert Smith, Wakefield, N. H.; Bellevue Hospital Medical College, New York, 1881; member of the Medical Society of the State of New York and of the American Psychiatric Association; was appointed assistant physician in 1882 at the city mental hospital located at Hart's Island, where he was superintendent from May 1, 1892 to Jan. 1, 1895, when he was transferred as superintendent to the New York City Farm for the Insane at Central Islip, which later became a unit of the Manhattan State Hospital and later a separate institution known as the Central Islip State Hospital, where he was superintendent and retired in December 1932 when he became superintendent emeritus; served for many years on the Governor's Lunacy Commission to examine before electrocution those convicted of murder; was at one time acting superintendent of the Pilgrim State Hospital, Brentwood, N. Y.; aged 83; died, January 6, in Garden City of acute coronary infarction.

Charles Manly Peters, Jersey City, N. J.; College of Physicians and Surgeons, Baltimore, 1913; also a dentist; consulting stomatologist from 1915 to 1922, attending oral surgeon from 1923 to 1939 and since 1940 consulting oral surgeon, Christ Hospital; chief oral surgeon, Jersey City Medical Center; chief maxillofacial surgeon, Margaret Hague Maternity Hospital; consulting oral surgeon, North Hudson Hospital, Weehawken, N. J., and St. Mary's Hospital, Hoboken; aged 62; died, Dec. 26, 1941.

Douglass William Montgomery ☉ San Francisco; College of Physicians and Surgeons, medical department of Columbia College, New York, 1882; member and in 1910 president of the American Dermatological Association; for many years professor of dermatology at the University of California Medical School; cofounder of the San Francisco Polyclinic and its first dermatologist; aged 82; died, Dec. 21, 1941, in Guayaquil, Ecuador, of coronary thrombosis.

S. Arthur Morris, New York; Columbia University College of Physicians and Surgeons, New York, 1918; member

of the Medical Society of the State of New York and of the American Society of Anesthetists, Inc.; past president of the New York Society of Anesthetists; on the staffs of the North Hudson Hospital, Weehawken, N. J.; Harlem Hospital, St. Elizabeth Hospital and the Lutheran Hospital; aged 51; died, January 5.

George Burton Stull, Harrisburg, Pa.; Medico-Chirurgical College of Philadelphia, 1906; member of the Medical Society of the State of Pennsylvania; past president of the Dauphin County Medical Society; was on the staffs of the Harrisburg Hospital and the Harrisburg State Hospital; served as company surgeon for the Pennsylvania Railroad; aged 63; died, Dec. 18, 1941, in Philadelphia of chronic lymphatic leukemia and streptococcal bacteremia following prostatectomy.

Walter Brown Orbin, Dormont, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; member of the Medical Society of the State of Pennsylvania; aged 63; died, Dec. 6, 1941, in the Presbyterian Hospital, Pittsburgh, of cerebral hemorrhage.

Thomas Madison Boyd ☉ Norman, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1917; served during the World War; formerly on the staff of the Central State Hospital; aged 47; died, Oct. 29, 1941, of pulmonary tuberculosis.

William Garrett Christoffersen, New York; Boston University School of Medicine, 1930; on the staff of the Veterans Administration Facility; aged 45; died, Oct. 25, 1941, of pneumonia.

Samuel Nason Newton, Versailles, Mo.; American Medical College, St. Louis, 1907; aged 66; died, Nov. 14, 1941.

DIED IN MILITARY SERVICE

Charles Joseph Young ☉ Cincinnati; University of Cincinnati College of Medicine, 1931; first lieutenant in the United States Army Medical Reserve Corps; aged 34; was killed, Dec. 16, 1941, in an airplane accident near Montgomery, Ala.

Benjamin Bennett Kysor Jr., Madrid, N. M.; University of Buffalo School of Medicine, 1937; first

BENJAMIN BENNETT KYSOR JR., M.D.

lieutenant in the medical reserve corps of the United States Army; aged 28; was killed in action recently at Corregidor Island, P. I.

Simm Hartt Moore, Houston, Texas; University of Texas School of Medicine, Galveston, 1907; member of the State Medical Association of Texas; served during the World War; was a lieutenant colonel in the National Guard, 111th medical regiment, 36th division, Camp Bowie, was serving at Camp Wolters where he died, Dec. 7, 1941, of coronary sclerosis, aged 55.

Correspondence

"ENDOCRINE TREATMENT OF CRYPTORCHISM"

To the Editor:—After reading the article on this subject by Thompson and Heckel (*THE JOURNAL*, Dec. 6, 1941, p. 1953) I must voice decidedly different opinions as to the proper treatment of youngsters with this condition.

The authors recommend the injection of chorionic gonadotropin from three to six times a week. This is continued from six to eight weeks on the average or until some growth in the genitals is produced. If under this treatment the testis or testes do not descend, immediate operation is advised. The authors feel a little uncertain how early in life this treatment should be instituted, but their observations suggest a very early age.

The authors admit that glandular therapy will not cause descent of a testis which will not descend spontaneously by puberty. This treatment, however, separates the cases that require operation; by means of glandular and operative treatment the testis is brought down into its normal position at an early age, which the authors believe is highly important. According to their experience a testis brought down into the scrotum by glandular or operative treatment is smaller than normal. They do not feel sure whether these testes are small because they have not descended normally or whether they have not descended because they were small. Because of the former possibility, they believe that the testis should be gotten down into the scrotum at as early an age as possible.

It would be unfortunate if the authors' recommendations were to be generally adopted, for this would entail a lot of needless glandular therapy and operations with useless expense and suffering. First, the great majority of undescended testes—and by this term I mean testes which cannot be palpated in the upper scrotum or in the inguinal canal but which lie within the abdominal cavity—descend spontaneously by the fifteenth year. In the small series reported by me (*Spontaneous Late Descent of the Testis*, *THE JOURNAL*, March 10, 1934, p. 759) eleven of the twelve testes eventually descended spontaneously. Johnson's report (*Cryptorchism*, *THE JOURNAL*, July 1, 1939, p. 25) of his experience in the examination of 31,609 boys confirmed my limited observations. Of the 544 cases encountered, 313 descended spontaneously during the limited period of observation. Some 154 boys were lost sight of and no follow-up examination was made on an additional 63. This was the first report I know of in which the natural course of unmolested undescended testes was followed in a large enough series to be convincing. Its perusal is recommended to those who question the frequency of spontaneous descent.

The testis that descends spontaneously but late is generally normal. This has been my experience, and Johnson reported that "spontaneous descent resulting in a normal testis as to size, consistency and position occurred in 300 instances." Presumably this was not the case in 13 cases. Another fact which I observed and which was confirmed by Johnson is that this spontaneous late descent occurs most frequently in the eleventh, twelfth, thirteenth and fourteenth years and an appreciable number in the fifteenth year. This fact should allay the urge that many seem unable to resist to institute active glandular or operative treatment at an early age.

Further, it has been shown that the undescended testis before puberty is indistinguishable microscopically from the normally descended one. Only occasionally is cryptorchism associated with evidence of glandular deficiency. Boys with one or both testes undescended are not in my experience "slightly frail and somewhat effeminate" in appearance. Either before or after puberty it would be impossible for any one to pick out of a

group of boys by their general appearance those whose only abnormality was an undescended testis or testes. In fact, the only boy in my group whose testis failed to descend eventually could lick any boy his age in the school. I doubt whether the idea that late descent of the testes is due to lack of hormone is tenable.

The question of the advisability of using glandular therapy before puberty in these cases deserves serious consideration. In my opinion one should think twice before undertaking any therapy that will produce enlargement of the genitals before puberty.

The authors were able to produce descent in only two of thirty-four intra-abdominal testes by glandular treatment. This to me makes it apparent that the response to glandular treatment does not designate those cases in which spontaneous descent would have occurred.

Briefly, it is my conviction that these youngsters with one or both testes undescended and no evidence of glandular disturbance should simply be observed until their fifteenth year. There can be no great objection to trying the effect of glandular therapy in the few remaining cases, although a certain number among the few remaining undescended testes will descend in the late teens and descend satisfactorily. Certainly operation has a limited field in the correction of uncomplicated cryptorchism.

CARL B. DRAKE, M.D., St. Paul.

NOTE.—The letter of Dr. Drake was sent to Dr. W. O. Thompson, who replies:

To the Editor:—We are still not convinced that Dr. Drake means the same thing we do by the term "undescended testis." The problem of diagnosis is important, and it is not always easy to distinguish true cryptorchism from pseudocryptorchism (migratory testis). In some instances of pseudocryptorchism the testis may retract into the abdomen, simulating intra-abdominal cryptorchism. In our experience migratory testes are frequently considered true undescended testes. At the onset of puberty these testes promptly take up a permanent location in the scrotum. Moreover, often after only a few doses of chorionic gonadotropin they will remain in the scrotum for a time and may become migratory again when the effect has worn off. It is because we have excluded migratory testes that our percentage of successful results with chorionic gonadotropin is so much lower than that reported by many other observers.

Dr. Drake states that the testes which he has observed that moved spontaneously into the scrotum at the age of 12 to 15 years were "generally normal" both in size and in microscopic appearance, whereas in our experience a true undescended testis is often smaller after it has been placed in the scrotum with glandular therapy or operative procedures than the testis which has been in the scrotum since birth. Migratory testes are often normal in size. These facts lead us to wonder whether Dr. Drake has failed to distinguish migratory testes from true undescended testes. It is difficult to see how the testes that Dr. Drake observed could have been normal unless they had been in the scrotum a considerable part of the time.

We can see no good reason to modify what we have said in our article under the subtitle "The Status of Glandular Therapy." In particular we should like to repeat the following arguments in its favor:

1. The testis can function normally only in the environment of the scrotum.
2. It is therefore logical to assume that the earlier it is brought into the scrotum the more likely it is to be normal.

WILLARD O. THOMPSON, M.D.

NORRIS J. HECKEL, M.D.

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in *THE JOURNAL*, January 31, page 400.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Feb. 9-11. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: Oral. Part II. Atlantic City, June 6-7. Final date for filing application is March 7. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: Oral. St. Paul, April, in advance of the meeting of the American College of Physicians, and Philadelphia, June, in advance of the meeting of the American Medical Association. Applications should be on file 6 weeks in advance of the date of oral examination. *Written.* Oct. 19. Final date for filing application is Sept. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: New York, June. Sec., Dr. R. Glen Spurling, 404 Brown Bldg., Louisville.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Oral. Part II. Groups A and B. Atlantic City, May or June. Final date for filing application is March 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: Oral. Baltimore, June 6 and Philadelphia, June 8. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY: Oral and Written. All Groups. Philadelphia, June, preceding the meeting of the American Medical Association. Final date for filing application is March 1. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha, Neb.

AMERICAN BOARD OF PEDIATRICS: Written. Locally, February 14. Sec., Dr. C. A. Aldrich, 707 Fullerton Ave., Chicago.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Oral. Boston, May 15-16. Final date for filing application is March 1. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Oral. All Groups. Atlantic City, June 4. Final date for filing application is April 1. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave., S. W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: Written. Part I. Various centers, March 2. Sec., Dr. J. Stewart Rodman, 225 S. Fifteenth St., Philadelphia.

Alabama Reciprocity Report

The Alabama State Board of Medical Examiners reports 6 physicians licensed to practice medicine by reciprocity from Nov. 6 through Dec. 8, 1941. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Loyola University School of Medicine.....	(1937)		Illinois
Louisiana State University School of Medicine.....	(1940)		Louisiana
Tulane University of Louisiana School of Medicine.....	(1939)		Louisiana
Johns Hopkins University School of Medicine.....	(1923)		Maryland
Washington University School of Medicine.....	(1939)		Missouri
Jefferson Medical College of Philadelphia.....	(1939)		Penna.

Arkansas Reciprocity Report

The Arkansas State Board of Medical Examiners reports 10 physicians licensed to practice medicine by reciprocity and 2 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners from July 7 through Dec. 31, 1941. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School.....	(1940)		Missouri
University of Illinois College of Medicine.....	(1939)		Texas
Boston University School of Medicine.....	(1936)		New York
University of Oklahoma School of Medicine.....	(1935), (1939)		Oklahoma
University of Pennsylvania School of Medicine.....	(1932)		Penna.
Medical College of the State of South Carolina.....	(1940)		S. Carolina
Memphis Hospital Medical College.....	(1903)		Tennessee
University of Tennessee College of Medicine.....	(1914)		Tennessee
University of Wisconsin Medical School.....	(1928)		New York

Tulane University of Louisiana School of Medicine.....	(1940)	
Duke University School of Medicine.....	(1939)	

Maine November Report

The State of Maine Board of Registration of Medicine reports the written examination for medical licensure held at Portland, Nov. 12-13, 1941. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Fifteen candidates were examined, 11 of whom passed and 4 failed. Five physicians were licensed to practice medicine by reciprocity and 8 physicians so licensed on endorsement of credentials of the National Board of Medical Examiners. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Georgetown University School of Medicine.....	(1933)		1
Harvard Medical School.....	(1938), (1939)		2

University of Nebraska College of Medicine.....	(1925)		Nebraska

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Use by Unlicensed Naprapath of Healing Art Title or Abbreviation.—An information was filed in the county court, Cook County, Ill., charging DeYoung, an unlicensed naprapath, with various violations of the Illinois medical practice act. The first count of the information charged that DeYoung did unlawfully diagnose an ailment or supposed ailment of a named person. The second count charged that he unlawfully treated the supposed asthma of the person referred to in the first count by manually "applying pressure and manipulating the back, side, vertebra and neck of the said person." The third count charged that he unlawfully suggested and recommended the manipulations referred to with the intent of receiving a fee therefor. The fourth count alleged that he unlawfully attached the title Doctor, Physician, Surgeon, M.D. or some other word or abbreviation to his name indicative that he was engaged in the treatment of human ailments as a business. The fifth and final count charged that DeYoung did unlawfully maintain an office for the treatment of human ailments. At the trial the patient referred to in the information testified that she went to DeYoung's home, on the porch of which was a sign "Dr. Joseph DeYoung, Naprapath." She consulted the defendant relative to some difficulty which she informed him she was having in breathing and told him that she suspected it was asthma or hay fever. DeYoung examined the patient in a room of his home which he used as an office. He pressed his fingers along her spine and told her that she did not have "much asthma" and gave her a massage treatment. The patient paid him \$5 for "half a course of naprapathic treatments" and he gave her a receipt signed "Joseph DeYoung, D.N." Before she left DeYoung's office and home he gave her three pamphlets, which were subsequently introduced in evidence at the trial. One pamphlet was entitled 'Bulletin of the American Naprapathic Association, Volume XII, Burlington, Iowa, September, 1936, Number 11' and contained articles by various persons as to the efficacy of naprapathic treatments for numerous conditions. At the top of the first page was stamped "Dr. Joseph DeYoung, Thornton, Ill." Another pamphlet was entitled 'The Business of Living' and advocated naprapathic treatments for the cure of many different human ailments. It was stated on the fourth page of this pamphlet that "Naprapathy is a scientific method of treating diseases both chronic and acute without drugs or surgery. Diseases and ailments which are regarded as incurable are cured by this wonderful treatment." On the last page of this pamphlet there was written in ink, 'Dr. DeYoung, Thornton, Illinois.' The other pamphlet was entitled 'A Personal Message' and consisted of questions and answers about naprapathy. The second question in the pamphlet was 'What is it?' and the answer, 'Naprapathy is a system of accurately charted manipulative treatment for the cure of human ailments.' On the next to the last page of this pamphlet it was represented that a long list of human diseases had been successfully treated by naprapathy. On the last page there was printed in heavy type, 'Dr. Joseph DeYoung, Naprapathic Physician, Thornton, Ill.' The second count of the indictment was quashed and the jury returned a verdict of not guilty as to the first, third and fifth count but found DeYoung guilty on the fourth count. Judgment was entered on the verdict and the defendant appealed to higher courts, the matter eventually reaching the Supreme Court of Illinois.

DeYoung contended that the fourth count of the information on which he was convicted should have been quashed because it did not allege that he was in fact engaged in the treatment of human ailments as a business. In answering this, the Supreme Court quoted from section 24 of the Illinois medical practice act reading, in part as follows:

If any person [1] shall hold himself out to the public as being engaged in the diagnosis or treatment of ailments of human beings, or [2] shall suggest, recommend or prescribe any form of treatment for the palliation, relief or cure of any physical or mental ailment of any person with the intention of receiving therefor either directly or indirectly any fee gift

or compensation whatsoever, or [3] shall diagnose or attempt to diagnose, operate upon, profess to heal, prescribe for, or otherwise treat any ailment, or supposed ailment of another, or [4] shall maintain an office for examination or treatment of persons afflicted, or alleged or supposed to be afflicted, by any ailment, or [5] shall attach the title Doctor, Physician, Surgeon, M.D., or any other word or abbreviation to his name, indicative that he is engaged in the treatment of human ailments as a business, and shall not then possess in full force and virtue a valid license issued by the authority of this State to practice the treatment of human ailments in any manner, he shall be guilty of a misdemeanor.

It will be noted, said the Supreme Court, that this section of the medical practice act defines five different crimes and the fourth count of the information on which DeYoung was convicted was based on the fifth crime stated in the section. The elements of that crime as defined in the statute are: (1) The person charged must have added the word "Doctor" or some other word or abbreviation to his name, (2) indicative that he was engaged in the treatment of human ailments as a business. This is not a declaration that the mere attaching of the title "Doctor" in itself conclusively establishes that the person charged was engaged in the treatment of human ailments as a business, but rather that the title or abbreviation must be attached and used in a manner and under such circumstances as to indicate that such person was so engaged. These are the only requirements of the fifth crime designated in the section quoted. In order to constitute the crime therein defined, it is not essential that the person charged actually be engaged in the treatment of human ailments as a business. Actual treatment without a license is a crime under a different clause of the section. There is no merit in DeYoung's contention that the fourth count is deficient because it does not contain an allegation that he was actually engaged in the treatment of human ailments as a business. Likewise there is no merit in his argument that the fourth count insufficiently set forth the acts charged to be a violation of the statute. That count charged the defendant, in the words of the statute, with violating it.

DeYoung next contended that the verdict of guilty as to the fourth count was repugnant to the verdicts of not guilty on the other counts. There is no merit in this contention, said the Supreme Court, for the specific charge made against DeYoung in the fourth count was separate and distinct from the charges made in the other counts.

The next question presented to the Court was whether or not the evidence showed beyond a reasonable doubt that DeYoung attached the titles "Dr." and "Physician" to his name in such a manner as to indicate that he was engaged in the treatment of human ailments as a business. Several of the witnesses called by the defendant, said the Supreme Court testified that naprapathy is merely massage of a particular type and that human diseases cannot be cured by this treatment. DeYoung testified that the title "Doctor" has many different meanings and may be used outside the field of medicine and that he had had the degree of "Doctor of Naprapathy" conferred on him. None of this testimony, continued the Court, tended to prove or disprove the allegations of the fourth count that the defendant attached the title "Dr." to his name indicative that he was engaged in the treatment of human ailments as a business. On two of the three pamphlets which were given to the patient who testified in this case either the defendant or some one in his household printed or wrote "Dr. DeYoung" without any qualification which would have shown that he was not a regular and licensed medical practitioner. On the third pamphlet, the name "Dr. DeYoung" was followed by the words "Naprapathic Physician." There was testimony which would warrant the jury's belief that the defendant gave these pamphlets to the witness even though he denied such a gift. In each of these pamphlets, representations were made that human diseases have been successfully treated and cured by naprapathic treatments. While DeYoung was not the author of these pamphlets, by attaching to his name as printed thereon the title "Dr." and by delivering them to the patient witness, he adopted the statements contained therein as his own and indicated that he was engaged in the treatment of human ailments as a business. In the opinion of the Court therefore, the offense charged in the fourth count was proved beyond a reasonable doubt.

The judgment of conviction was accordingly affirmed.—*People v. DeYoung*, 38 N. E. (2d) 22 (Ill., 1941).

Dental Practice Acts: Suspension of License for Advertising Statements of a Character Tending to Deceive or Mislead the Public.—The California dental practice act authorizes the board of dental examiners to revoke or suspend the license of a dentist guilty of unprofessional conduct, which, among other things, the act defines as "The making use of any advertising statements of a character tending to deceive or mislead the public." On a charge that Smulson had so advertised, the board, after notice and hearing, suspended for two years his license to practice in California. He sought a writ of mandate from the superior court, Los Angeles County, to compel the board to vacate its order suspending his license. From a judgment for the board, Smulson appealed to the district court of appeals, second district, division 1, California.

Smulson contended that the provision of the dental practice act under which his license was suspended is too vague and uncertain to enable a dentist to know what is forbidden and is therefore void. The act, said the court, here in question provides suspension or revocation of the license of a dentist making use of any advertising statements of a character "tending to deceive or mislead the public." The words of this provision are well known and understood in both popular and legal language. This description of the forbidden practices is no more uncertain than many other statutory provisions which have been held to be valid exercises of legislative power. It is not required that even a penal statute, to be valid, have that degree of exactness which inheres in a mathematical theorem. The law is full of instances in which a man's fate depends on his estimating rightly, that is, as the jury subsequently estimates it, some matter of degree. A case very similar to the present one, said the court, is *Glass v. Board of Medical Examiners*, 50 Cal. App. 389, 195 P. 73, which upheld a provision of the medical practice act defining unprofessional conduct for which a license could be revoked as including "all advertising of medical business which is intended or has a tendency to deceive the public or impose upon credulous or ignorant persons, and so be harmful or injurious to public morals or safety." The court in the *Glass* case said:

It would not be possible to frame a definition of unprofessional advertising which would anticipate in terms every form of advertisement which unscrupulous practitioners might thereafter devise. This being so, it cannot reasonably be held necessary to the validity of the statute that it go further than to state a reasonably definite rule under which all such specific acts might be included. This we think has been done in the terms of the statute so far as the same are now presented for consideration.

The charges on which the board proceeded in the proceedings against Smulson alleged that he "knowingly and intentionally caused to be printed, circulated and distributed to the general public . . . a certain hand bill . . . wherein and whereby the said Harry Smulson did advertise as a dentist and did make use of advertising statements of a character tending to deceive or mislead the public, a photostatic copy of which advertisement is hereto attached." Smulson contended apparently that the charges were insufficient but for just what reasons the reported decision does not make clear. In proceedings, said the appellate court, before a licensing board for revocation or suspension of a professional license on account of unprofessional conduct the accusation or complaint is sufficient if expressed in the language of the statute. This rule is subject to the qualification that the language of the statute must be sufficiently explicit to advise a person charged thereunder of the particular kind of unprofessional conduct which it is proposed to prove against him. Here the language of the statute used in the accusation would of itself be sufficient to comply with the rule, as so qualified, but the accusation goes further and sets forth a copy of the advertisement used and characterizes it in the statutory language.

In describing the advertisement attached to the complaint, the appellate court said: "As is usual in such cases it is grossly and fulsomely laudatory of [Smulson's] mode of operations and of the quality of the work done by him." Referring to dental plates, the attached advertisement said: "They are made after Dr. Smulson personally takes the impressions and makes a special study of your case. What I have done for thousands of other folks I am confident I can do for you." The statements just quoted, said the appellate court, read with the other matters commendatory of Smulson's work in the advertisement,

convey the idea that it is too important a part of the practice to be left to the "skilled work of only licensed dentists" in Smulson's office, and so it is done by Smulson personally. A witness who testified at the hearing before the board stated that she had gone to Smulson's office for plates in response to this particular advertisement and that the impressions of her mouth were not taken by Smulson but by some dentist in his employ. Obviously, said the court, the declaration in the handbill or advertisement did not represent a uniform custom of his business and tended to mislead the public in a matter which in the handbill he tried to make it think was important. Smulson endeavored escape from this conclusion by urging that the word "take" in the statement quoted did not refer to the actual making of the impressions but meant that after they are made Smulson "takes" them in his hands for the purpose of studying them. To any one who has heard any discussion of such matters, continued the court, this is plainly a forced and unusual construction of the language used. Even if it be accepted as a possible construction, it remains true that the construction we have given the word "take" in this connection, as referring to the actual work of making the impressions, is also possible and much more in consonance with ordinary usage.

The handbill or advertisement also contained these statements: "You can have your plates and make your first payment 30 days after they are completed by using my no money down easy payment plan"; "Don't Pay Me One Penny Until You Have Worn My Dental Plates for 30 Days." These statements, said the court, were also misleading. According to Smulson's testimony, the easy payment plan referred to consisted in taking a note, which he required the patient to sign, and selling it to a finance company, first submitting the application for credit to that company before doing the work. The date of the first payment was put in the note when the patient made a definite appointment for the work and was fixed so as to be thirty days after the then estimated time for completion. One witness before the board testified that the time for her first payment on the note arrived and she was sued on the note before she got one of her plates fixed up so that she could wear it. In Smulson's actual practice, he fixed the date of the first payment before he even began to work on the plates; at that time he could not know when he could complete the plates and have them in wearable condition, for sometimes many fittings with accompanying delay would be necessary for that purpose. But once the date of payment was fixed and the note transferred to a finance company, it was out of his power to extend the time to conform to his statements in the handbill.

The order of the board of dental examiners suspending Smulson's license was, in effect, affirmed.—*Smulson v. Board of Dental Examiners*, 118 P. (2d) 483 (Calif., 1941).

Society Proceedings

COMING MEETINGS

Annual Congress on Medical Education and Licensure, Chicago, Feb. 16-17.

American Association of Anatomists, New York, April 1-3. Dr. Eliot R. Clark, Dept. of Anatomy, University of Pennsylvania School of Medicine, Philadelphia, Secretary.

American Association of Pathologists and Bacteriologists, St. Louis, April 2-3. Dr. Howard T. Karsner, 2085 Adelbert Rd., Cleveland, Secretary.

American Orthopsychiatric Association, Detroit, Feb. 19-21. Dr. Norville C. LaMar, 149 East 73d St., New York, Secretary.

American Physiological Society, Boston, March 30-April 4. Dr. Carl J. Wiggers, 2109 Adelbert Rd., Cleveland, Secretary.

American Society for Experimental Pathology, Boston, April 1-3. Dr. Harry P. Smith, Medical Laboratory Bldg., Iowa City, Secretary.

American Society for Pharmacology and Experimental Therapeutics, Boston, March Secretary.

Minnesota Medical Society, 12. Dr. Paul W. Secretary.

American Society, Wood, Room 150 Dr. George M. Secretary.

Central Surgical Curtis, Ohio St Secretary.

Federation of American Societies for Experimental Biology, Boston, March 31-April 4. Dr. D. R. Hooker, 19 West Chase St., Baltimore, Secretary.

Mid South Post Graduate Medical Assembly, Memphis, Tenn., Feb. 10-13. Dr. Arthur F. Cooper, 165 Madison Ave., Memphis, Tenn., Secretary.

Pacific Coast Surgical Association, San Francisco and Del Norte, Calif., Feb. 17-20. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Society of University Surgeons, Cincinnati, Feb. 12-14. Dr. Frank Glenn, 525 East 68th St., New York, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Irradiation of Pituitary Gland.—Pendergrass and his associates state that they have irradiated the pituitary gland of 31 patients with high blood pressure and of 10 with symptoms referable to menopause or menstruation. Blood studies of almost every patient for the antidiuretic substance prior to irradiation gave positive results. Approximately half the patients were clinically improved after irradiation of the hypophysis. In about two thirds of the patients irradiating the pituitary caused the positive results of antidiuretic tests to become negative. This suggests that there may exist in the region of the hypophyseal fossa a center or centers which partially control the antidiuretic substance of the blood. There is evidence that the pars neuralis (posterior lobe) liberates this substance. Other authors believe that the hypothalamus and

its supraoptic nuclei may do so. As far as roentgen therapy is concerned it is immaterial which area liberates the substance, as both are included in the field of irradiation. Study suggests that as the dose is increased to about 500 roentgens more positive results of antidiuretic tests become negative. In some persons the reaction may become negative with 80 roentgens delivered to the skin of the temple, whereas doses as high as 1,600 roentgens will have no effect on others. The beneficial effects were due at least in part to the effect of irradiation on the basophilic infiltration, as basophilic hypophyseal tumors are known to be radiosensitive. Much more investigation will be necessary before the value of the antidiuretic tests in the treatment of hypertension and in the retention of catamenial fluid can be evaluated.

Pneumoperitoneum as Aid in Pelvic Irradiation.—When treating carcinoma of the cervix Sante displaced the intestine from the field of radiation by inducing pneumoperitoneum. He points out that with the patient in the Trendelenburg position, the air rises into the pelvis, envelops the pelvic structures and displaces the intestine to the upper portion of the abdomen. Such removal of the underlying intestinal structures from the field of radiation aids compression of the lower part of the abdomen by the treatment cone. Compression alone increases the relative depth dose. After the intestinal tract has been emptied, pneumoperitoneum is induced by inflation with air to a point somewhat greater than that ordinarily used for diagnostic pneumoperitoneum. The patient should be kept on her back in bed for the first day or until she becomes accustomed to the presence of air in the abdomen. Air is used because large amounts of it usually take ten to fourteen days for complete absorption and often the entire course of roentgen therapy can be carried out with a single filling. At most, one refill about the seventh day may be necessary. Vaginal measurements seem to indicate that irradiation of the adnexal regions is more adequate when pneumoperitoneum is induced and when the Trendelenburg position is used than when the usual method of external irradiation is employed. Constitutional reactions, even with five daily external ports and one vaginal port of irradiation, did not develop when the intestine was properly displaced and excluded from the field of irradiation.

New Carbon Dioxide Absorbent.—Kilborn states that a new carbon dioxide absorbent, Baralyme, has been used for more than 1,000 patients given cyclopropane for surgical anesthesia. The results show that Baralyme has the following advantages over soda lime: Its efficiency is greater. The concentration of carbon dioxide is practically zero per cent up to the time of beginning exhaustion. No rest periods are needed. Its non-caustic quality removes the hazard of burns of the face and mucous membranes. The lower heat generation of Baralyme (110 F. as against 154 F. for soda lime) means less heat reflection back to the patient, especially in the to and fro method. A high concentration of carbon dioxide while Baralyme is used indicates exhaustion. No false temporary peak occurs, and the possibility of discarding the absorbent prematurely is precluded. The life of Baralyme per unit of volume averages 35 per cent longer than that of soda lime. Baralyme does not emit an unpleasant odor.

Hypertensive Heart Disease of Long Duration.—Flaxman presents histories of 11 patients who lived ten to twenty (average thirteen and seven-tenths) years after the first appearance of hypertensive heart disease at 56, 64, 52, 55, 35, 39, 47, 61, 50, 25 and 34 years, respectively. These patients escaped the usual unpredictable and uncontrollable causes of death (cerebral hemorrhage, coronary thrombosis and uremia) in hypertensive heart disease. Physical incapacity, the first factor, was not too great in the patients because their congestive heart failure was controlled by digitals and none had the anginal syndrome. The character of the patient's work, the second factor, was important in only 2, a laborer and a salesman (of the other 8, 6 were housewives and 2 were unemployed). The salesman worked for ten years after his symptoms appeared but being his own employer he worked only enough to support himself. The laborer worked for fifteen of twenty years at a highly seasonal occupation, being employed probably not more than six months out of every year. Another consideration that entered into the reasons why these 2 patients continued to work was that they had no fear of heart disease as an incapacitating or a fatal ailment. The influence of disability insurance as an incapacitating factor need not be considered, as none of the patients had any policies. Disability in heart disease depends on the attitude of the patient in relation to his work and activity, and on the type and severity of his symptoms as related to necessary effort.

Screening for Tuberculosis in the Civilian Population.—Douglas and Birkelo, from their experience with the 4 by 5 inch fluorograph of the chest of 15,220 persons, conclude that the method is reasonably accurate for detecting pulmonary tuberculosis. Surveys of community groups are definitely profitable as many previously unrecognized cases are discovered. They believe that a wider application of the method will aid in the control of tuberculosis. Of the 15,220 fluorographs, 8,322 were taken during the Brewster project, 4,727 were of pregnant women, 751 were of housekeepers and 1,420 were of young persons selected for the National Youth Administration. The fluorographs revealed a total of 163 cases of pulmonary tuberculosis: 121 in the first, 29 in the second, 4 in the third and 9 in the fourth group of persons examined. The tuberculosis was primarily active in 27, minimal in 45, moderately advanced in 42, far advanced in 32 and milary in 3, and in 14 there was pleurisy with effusion.

Carbon Disulfide Absorption.—Lewey applies the term 'chronic carbon disulfide absorption' to the syndrome observed in 120 viscose rayon workers. All but 3 of the workers were working at the time of the examination and did not consider themselves ill although they admitted various complaints when specifically questioned. No one symptom or sign was characteristic of the absorption, but signs of peripheral and cranial nerve involvement were elicited in 76 per cent, psychic symptoms (sleeplessness and bad dreams followed by fatigue, listlessness and loss of initiative) in 71 per cent, optic signs in 54 per cent, tremor in 33 per cent and pyramidal and extra-

pyramidal signs in 21 per cent. The total serum cholesterol was often definitely increased and the esters were simultaneously decreased. The thiamine excretion tended to be low. The spinal fluid was normal. The hypothesis offered (supported by experiments on dogs) is that the mechanism of chronic carbon disulfide absorption is different from that of acute carbon disulfide intoxication. The first is attributed to thiamine deficiency, possibly by way of hepatic damage and by direct poisoning of the coenzymes of nerve metabolism and respiration, whereas the second is compared to the narcotic effect of other gaseous anesthetics. A diet rich in vitamin B in the cafeterias of plants using carbon disulfide is recommended.

Neuromuscular and Muscular Disorders.—DeJong has used alpha tocopherol and wheat germ oil in treating 19 patients with amyotrophic lateral sclerosis, 1 with amyotrophic lateral sclerosis associated with syphilis, 5 with progressive spinal muscular atrophy, 8 with pseudohypertrophic muscular dystrophy and 2 with recent extensive poliomyelitis. The only outstanding clinical changes in amyotrophic lateral sclerosis and progressive spinal muscular atrophy with progressive bulbar paralysis have been a slight decrease in the fibrillary tremors, a feeling of well-being, a slight gain in weight and in some patients a subjective temporary increase in muscular strength. Large doses of alpha tocopherol were of no benefit in far advanced muscular dystrophy. There was no definite acceleration of improvement in poliomyelitis and no regeneration of atrophic muscles. Amyotrophic lateral sclerosis, progressive spinal muscular atrophy and progressive bulbar paralysis are degenerative diseases, and the atrophy in them is secondary to degeneration of the motor neurons. Therefore, regeneration of such muscles can follow only after the motor neurons are regenerated.

Lesions from Sulfathiazole.—According to Climenko and his co-workers, the daily medication with 1 Gm. of sulfathiazole per kilogram of body weight caused the death of 4 of 5 adult Macacus monkeys during the course of medication which was

planned to be continued for twenty-eight days. The kidneys of the animals were edematous and moderately congested. On section, there were collections of crystalline material in the larger collecting tubules. Five other animals on the same dose level of sulfathiazole which were given also a gram for gram equivalent of sodium bicarbonate survived the twenty-eight days of medication without any untoward signs but moderate diarrhea. Two of these animals were killed on the twenty-ninth day, and no gross pathologic lesions were observed in the kidneys at necropsy. On section, the kidneys revealed slight acute congestion. The lumens of the convoluted tubules contained fluid and small accumulations of hyaline bodies, which in no way resembled the crystalline material seen in the animals given sulfathiazole alone. Foci of acute inflammation were not found. The clearcut differences between the two groups of animals cannot be accounted for in terms of difference in blood concentration, for the simultaneous administration of an alkali with sulfathiazole tends to improve the absorption of the drug from the gastrointestinal tract. The difference was evidently dependent on the hydrogen ion concentration of the urine. From previous experimental work, the authors know that the amount of sodium bicarbonate given 5 monkeys maintained the pH of the urine between 7.2 and 7.4. They suggest that in clinical practice a sufficient amount of sodium bicarbonate (or another suitable alkali) to maintain the urine on the neutral alkaline side should be used with sulfathiazole medication. Sulfathiazole and its conjugated derivative acetylsulfathiazole are many times more soluble in alkaline mediums than they are in acid mediums. Alkalinity of the urine prevents precipitation of the drug in the kidney, and thus the formation of local lesions is prevented.

Lansing Poliomyelitis.—Peers observed that the pathologic lesions in the brain of a youth of 19 in whom poliomyelitis due to the Lansing strain of the virus developed were essentially similar to those produced in monkeys by the virus isolated from the cerebral tissue of the youth. In spite of the supposedly low susceptibility of monkeys, the disease in them was anatomically more severe than in the human subject. The difference is really great, as all the animals were killed when paralysis was well established rather than after the disease had run its natural course. Since the intracerebral route of inoculation was used the severe lesions observed in the cortex and basal ganglions may be accounted for, but the extensive damage in the midbrain, cerebellum and medulla is not so easily explained. The pattern of the fully developed disease was essentially identical in man and in the monkey, though the route of inoculation was obviously different.

Protein in Urine and Bright's Disease.—Blackman and his associates demonstrate a relation between the concentration of total protein and of globulin in the urine and the development of renal insufficiency in patients with Bright's disease. The determination of these concentrations in 42 patients indicated that in the patients who recovered, and in others during periods when renal function remained stationary, either the urine usually contained a small amount of protein (less than 0.5 Gm. per hundred grams of tissue) or if a larger proportion of protein was present there was only a small proportion of globulin (less than 35 per cent). The urine of patients in whom progressive renal failure developed more often contained a higher concentration of protein, of which a larger proportion was more often found to be globulin. In patients with the chronic form of the disease the more often both total protein and globulin were found in high concentration the more rapid was the progress of renal insufficiency.

Five Day Treatment of Syphilis.—From an analysis of the published results of the five day intravenous drip method of treating early syphilis Epstein concludes that the method is entirely experimental and should be employed only in properly equipped and adequately staffed institutions. The method sterilizes the infectious lesions of early syphilis within twenty-four to forty-eight hours. Since only five days are required for the treatment all patients complete the course, in contrast to the 20 to 80 per cent of the patients treated by the usual methods who disappear from observation before therapy is completed. Satisfactory therapeutic results are as frequent as with other methods now in use. The technic accomplishes the primary aim of Ehrlich. The disadvantages of massive arsenotherapy in early syphilis are that: The treatment is still in the experimental stage. It is a hospital procedure and entails considerable expense. Sufficient time has not elapsed to evaluate its final results and the toxic end effects. Neoarsphenamine is too toxic to be practical, and the therapeutic results obtained with mapharsen have not been as satisfactory as those following the use of neoarsphenamine. The method has been employed only for male patients with early syphilis. No data are available on its value in female patients, for latent syphilis or for the numerous manifestations of late syphilis. The author disagrees with the statement that 2 instances of hemorrhagic encephalitis with 1 death among the 350 patients so treated is not excessive.

Allergic Disease.—Sheldon and his associates used histamine-azo-despecciated horse serum globulin for the treatment of 76 patients having atopic eczema, contact dermatitis, physical allergy, seasonal hay fever, perennial allergic rhinitis, gastrointestinal allergy or migraine headache. Many of the subjects manifested two or more types of allergic symptoms. The histamine azoprotein was tested intracutaneously in doses of 0.02 cc., and if a delayed reaction was absent the first treatment consisted of giving 0.05 cc. of undiluted histamine azoprotein subcutaneously in the deltoid area. Each subsequent dose, given twice a week, was increased by 0.5 cc. until symptomatic relief was obtained, or until a 1 cc. dose was reached. The initial dose for patients with delayed reactions was greatly reduced, and subsequent increases were guided by symptomatic improvement or the local reaction. No important local or systemic reactions followed the use of histamine azoprotein. The therapeutic results were sufficiently good to warrant further investigation. Best results were obtained by patients with physical allergy and cutaneous hypersensitivity. Two asthmatic patients, in whom asthma could be induced by exposure to cold, were relieved after three weeks of treatment. Asthma can no longer be produced in these 2 subjects. One patient, so sensitive to sunlight that she was confined to her home during daytime, is now able to do as she desires. In the few patients with contact dermatitis the cause was limited to but a few substances, but it appears that histamine azoprotein in conjunction with local treatment has more to offer than any other form of therapy. The patients with atopic eczema seemed to show definite benefit from histamine azoprotein therapy. Patients with seasonal ragweed hay fever were benefited as much as were similar control patients receiving specific ragweed desensitization in 1940. Histamine-azo-despecciated horse serum globulin is not offered as a panacea for allergic diseases.

Speed of Action of "Slow Epinephrine."—From their observations following one hundred and twenty injections of "slow epinephrine" (in oil) given to 36 ambulatory patients Bacon and his colleagues conclude that epinephrine in oil is not slow in its action, that the time between its administration and its pharmacologic effect compares favorably with equivalent doses of aqueous epinephrine and that contrary to the general belief small doses of epinephrine in oil frequently are effective. There was a response within fifteen minutes after nine of fourteen injections of 0.2 cc. of epinephrine in oil, within ten minutes after sixteen of twenty-six injections of 0.3 cc., within ten minutes after twenty-three of forty-four injections of 0.5 cc., within ten minutes in eleven (within fifteen minutes after twenty-three) of thirty-three injections of 0.6 to 0.8 cc. and within ten minutes after fifteen of twenty-five injections of 1 to 1.5 cc.

Sensitivity to Human Dander.—Hampton and Cooke present studies which suggest that sensitivity to human dander and eczema are related, that is, that the sensitivity is the result rather than the cause of eczema. They observed that the skin of 30 of 33 patients with eczema reacted to human dander extract and that the serum contained skin-sensitizing antibodies for it. Patients with eczema usually showed positive reactions, while

noneczematous persons usually showed negative reactions. The serum of only 10 of 90 patients with allergic diseases other than eczema contained skin-sensitizing antibodies. The serum of 10 normal, nonallergic patients did not contain skin-sensitizing antibodies. Only 3 of 75 patients with dermatoses other than eczema reacted significantly to human dander extract. As no relationship was found between sensitivity to human dander and that to other animal danders, it appears that general sensitivity to a component, such as keratin, common to all animal danders does not exist. If the sensitivity to human dander is based on extensive or prolonged inflammation of the skin only the patient with an allergic constitutional background is capable of producing the antibodies to human dander extract. Consequently, persons with eczema, being allergic, produce these antibodies, while those with psoriasis, seborrhea, tinea and exfoliative dermatitis, being nonallergic, do not. This view is supported by the fact that sensitivity to human dander was found in 1 patient with psoriasis and in 1 with tinea, both allergic but without eczema.

Toxic Reactions to Sulfapyridine.—Goldbloom and his associates observed unusual toxic reactions of the blood to sulfapyridine, varying grades of the leukemoid blood picture and associated secondary thrombocytopenic purpura in 3 patients with acute hemolytic anemia. In spite of these reactions, the patients recovered in a short time after transfusions of blood were given. Studies of the bone marrow showed erythroblastic hyperactivity in 2 patients. The authors believe that the decided hemolytic anemia may be evidence of a peripheral action, the leukocytosis an irritation of the myeloid element of the bone marrow and the thrombocytopenic purpura an allergic phenomenon. The reactions in their patients emphasize the importance of making frequent blood counts for any patient receiving sulfapyridine.

Endocrine Aspects of Headaches.—Goldzieher investigated the possible causal relationship between endocrinopathies and attendant metabolic disorders in 50 consecutive patients with severe headaches. All the patients, including the few whose headaches were not typically migrainous, had no organic or systemic disease as a possible cause of the headaches. Chemical studies, determination of the basal metabolism and observation of the daily urinary output show evidence of a general trend of retention of sodium chloride and water and frequent stigmas pointing to an endocrine background. These stigmas were a lowered basal metabolism, a decreased specific dynamic action of proteins, a relative lymphocytosis, a high value for uric acid, sodium and chloride in the blood, a low blood sugar level and abnormalities in the configuration of the sella turcica. Endocrine headaches, including migraine headaches, are explained as the result of increased intracranial pressure. They develop when an increased permeability of the capillaries permits an increased flow of water to, and subsequent retention in, the tissues in which abnormal quantities of sodium salts have been stored. The successful treatment of endocrine headaches consists of a high

protein diet with a restricted intake of salt, liquid and carbohydrate, of medication with ammonium or potassium salts and belladonna preparations, and of remedying the endocrine deficiency with thyroid and pituitary extracts.

Multiple Invasion of Blood Stream.—Kanof and Kramer found more than one organism in the blood stream of 24 children with bacteremia during hospitalization. These 24 patients represent 8 per cent of the 320 patients with bacteremia encountered during five years. There were 9 patients with true mixed septicemia, 5 with septicemia complicated by secondary bacteremia and 10 with spurious mixed septicemia, in which the second organism was a variant of the first or in which a casual invader appeared in the course of sepsis. It appears that once the resistance of the body to invasion of the blood stream is overcome any number of organisms may follow the first invader. The immunologic changes which permit the onset of sepsis are specific for one organism. Invasion by more than one organism rarely takes place, but when it does occur it is observed only in extremely young infants and invariably has a fatal outcome. Two points of special clinical interest are the appearance of an erysipeloid rash when hemolytic streptococcemia is superimposed on existing sepsis and the difference in the clinical course of true mixed septicemia and septicemia complicated by secondary bacteremia. When two organisms are present in the same blood an unusually long incubation period is followed by a short, acute course that terminates rapidly in death, but when the second invasion is complicated by primary sepsis the incubation period is short. The illness is characterized by two septic periods separated by an afebrile period; the second is coincidental with the second invasion.

Menopausal Symptoms.—Peelen gave diethylstilbestrol orally to 30 patients with menopausal symptoms. The drug was taken for fourteen days to ten months. The initial daily dose was 1 mg. This was reduced shortly afterward to 0.5 mg. daily. The latter dose was to be taken for two weeks, but if nausea developed it was to be discontinued for one day and then resumed the next day. The menopausal flushes were usually held in abeyance after one week of treatment. The maintenance dose was then determined, and in most instances three to seven 0.5 mg. capsules weekly were sufficient. There was no consistent difference between the maintenance dose necessary to control the symptoms of surgical and that necessary in natural menopause. One patient, after only two weeks of treatment, remained free of symptoms for six months. One patient with senile vaginitis experienced relief from hot flushes with 0.5 mg. of diethylstilbestrol daily. However, the vaginitis did not improve until the dose was increased. After she had taken 1 mg. daily for ten days mature cornified epithelial cells appeared in the vaginal mucosa and the inflammation subsided. Of the remaining 28 patients 22 were relieved, 3 were partially relieved and 3 experienced no relief. Two of the 30 patients were unable to take the drug because of nausea and vomiting. These manifestations disappeared within twenty-four hours after the drug was withdrawn but recurred promptly when diethylstilbestrol was again administered. Three patients experienced slight nausea when diethylstilbestrol was given daily, but reducing the dose to 0.5 mg. two to four times a week relieved the flushes and the nausea did not recur. One patient had headaches when taking 0.5 mg. of diethylstilbestrol daily but had no difficulty when the same amount was taken on alternate days, and she continued to remain almost completely free from her previous menopausal symptoms.

Respiratory Infections.—According to Menefee and Speed, during the influenza epidemic of January and February 1941, 116 students at Duke University with mild influenza were treated symptomatically and 111 were given an initial dose of 2 Gm. and then 1 Gm. of sulfathiazole every four hours until the temperature had been normal for twelve hours. The average duration of fever of the 111 students from the time of admission was one and six-tenths days. The average total dose of sulfathiazole was 13.5 Gm. The average stay in the hospital was three and four-tenths days. The figures for the group treated symptomatically were at least twice as great. Thirty-four per cent of the 111 treated patients complained of nausea and a sensation of "drunkenness." However, the symptoms were severe in only 2, and 1 patient complained of pain in the region of the right kidney after receiving 15 Gm. of sulfathiazole; the drug was withdrawn and the pain disappeared forty-eight hours later. Leukopenia, hemolytic anemia, cutaneous rash, drug fever or erythema nodosum did not develop in any of the patients. Pneumonia developed in 1 patient eight days after the receiving of the drug, in 2 symptomatically treated patients and in 2 completely untreated patients.

Gastrointestinal Tract in Hyperthyroidism.—Brown and his colleagues compared the changes in the gastrointestinal tract in 24 hyperthyroid patients and 14 normal controls and concluded that the following changes are characteristic of hyperthyroidism: (1) an increased frequency of achlorhydria, (2) an increased prominence of the gastric rugae, (3) an increase in the rapidity with which the stomach starts to empty, (4) a delay in the gastric emptying time and (5) increased tone and motility of the small and the large intestine.

Synthetic, Nonabsorbable Suture Material in Surgery.—Narat appraises the value of two nonabsorbable suture materials, zytol, or nylon, and vinyon, a derivative of resin vinylite. Each material was used in 30 unselected, consecutive, clean, major operations. The two materials were used as continuous sutures for closure of peritoneum and skin, but the fascia was sutured with interrupted stitches. There was no evidence that the tissues were irritated. At the end of seven to ten days the abdominal wounds were completely healed and there was no sign of inflammatory reaction. Vinyon or zytol and catgut were never employed together. Vinyon and zytol are extremely pliable, can be easily and repeatedly sterilized, do not fray, have a tensile strength which is not impaired when they are wet, are not attacked by pathogenic micro-organisms, are not susceptible to action of tryptic enzymes, are apparently nonallergic and are inexpensive. Investigation is necessary to establish their value in infected or contaminated wounds.

Peristalsis of Common Bile Duct.—Macdonald visualized peristalsis of the common bile duct under the fluoroscope in a man while a study was being made of a pathologic common bile duct. This was immediately recorded roentgenographically. The roentgenograms show conclusively that the possible causes of the changes in the internal diameter of the common bile duct are probably irritation by the T tube, extension of the tissue of the sphincter of Oddi into the duct and active peristalsis. Irritation could not produce such changes unless the inherent ability to contract and relax was present. It is unusual for sphincter tissue to extend so far up the duct. Therefore, in Macdonald's patient the common bile duct had the ability to move its contents onward by active effort. Fluoroscopic study showed that the shadow of the dye was changed in shape by a temporary constriction, and that some iodized oil distal to the constriction was rushed forward into the duodenum. The author believes that peristalsis should be expected in the common duct because the duct is an integral part of one of the most important physiologic functions of the body and an uninterrupted onward flow of bile is essential to good health, and that there must be some mechanism, other than back pressure, to overcome transient states of obstruction.

*Some Factors Affecting Incidence of Postanesthetic Vomiting R M Davies—p 578

Night Blindness and Mental Disorders.—Wittkower and his collaborators investigated histories of 52 soldiers from 19 to 50 years of age, complaining of night blindness, 39 were less than 30, 1 was an officer, 8 were noncommissioned officers and 43 were privates. Nine had had night blindness since childhood 16 for several years, 13 noticed difficulty in seeing for the first time in the blackouts preceding the war and 14 have had difficulty since the war. Forty-two of the men were examined at the eye department of a military hospital. The study of 13 gave negative results, 6 were "one eyed" (2 had had one eye removed earlier in life, and in 4 one eye was defective because of trauma, inflammation or amblyopia, but the good eye of these 6 men presented no cause for the night blindness). 11 had slight errors of refraction with good vision with glasses and fair vision without glasses. 11 had moderately high errors of refraction and 1 had degenerative choroidoretinitis involving the peripheral parts of both fundi. Of 40 men tested dark adaptation was grossly defective in 4, defective in 11, subnormal in 16, low normal in 8 and high normal in 1. The dark adaptation of 33 younger and more intelligent soldiers chosen at random was grossly defective in 1, defective in 1, subnormal in 8, low normal in 13 and high normal in 10. Psychiatric examination of the 52 soldiers revealed that they were psychologically abnormal, and that the abnormality was far beyond that expected in the average population. Apart from the night blindness, most of them were unfit for military service, 9 patients had minor psychologic disorders that were not sufficient to interfere with an ordinary mode of life. 14 had acute and 13 chronic anxiety states, 8 had conversion hysteria, 4 had depression, 3 had schizoid or overaggressive psychopathic personalities and the disorder of 1 could not be classified.

Incidence of Postanesthetic Vomiting.—Davies believes that postanesthetic vomiting is influenced by the operative procedure, the sex of the patient and the anesthetic. From the records of 1,000 unselected patients who were operated on under various anesthetics it was observed that 2.6 per cent had nausea only, 15.7 per cent vomited once, 20.9 per cent vomited two to five times, 6.5 per cent vomited more than five times within eighteen hours and 0.8 per cent vomited more than five times in more than eighteen hours. Of four groups of 100 patients each (given respectively, nitrous oxide oxygen and ether, pentothal sodium, nitrous oxide and oxygen, pentothal sodium, nitrous oxide, oxygen and ether, and pentothal sodium cyclopropane, nitrous oxide, oxygen and ether) 3 per cent of the first group had nausea only, 17 per cent vomited once, 31 per cent vomited twice, 11 per cent vomited three times and none vomited four times, and 68.6 per cent of the women vomited as against 45.5 per cent of the men. The respective percentages for the second group were 6, 15, 20, 5, 0, 56.5 and 26, for the third group they were 0, 17, 21, 4, 0, 52 and 39.6, and for the fourth

group the percentages were 1, 10, 10, 6, 1, 26.5 and 10. A study of nausea and vomiting occurring in patients who had operations on the nose, nasopharynx and mouth does not bear out the remark that "patients are always sick after tonsillectomy." A study of minor gynecologic operations (dilation and curettage) revealed that the anesthetic had little effect on the incidence of vomiting but that dilation raised the incidence. The preoperative therapeutic factors capable of reducing the vomiting are absence of food in the stomach, avoidance of excessive purging, proper premedication combined with a basal hypnotic, substitution of pantopon (the hydrochlorides of the alkaloids of opium, principally morphine) for morphine and adequate doses of atropine and scopolamine to prevent secretion and consequent swallowing of saliva and mucus. Favorable postoperative factors are reception of fluids rectally or even orally, avoidance of anoxemia, engaging in as little movement as possible immediately after the patient's return to bed, sedation with soluble pentobarbital and the right lateral position in bed.

Calcium in Autohemagglutination.—Parish and Macfarlane state that autohemagglutination occurred in a healthy man of 27 when his blood was withdrawn into citrate or oxalate at room or colder than room temperature. The reaction was reversible, for the clumps disappeared when the blood was warmed to body temperature and reappeared when cooled. Agglutination did not occur when the patient's serum was mixed with cells which were washed in physiologic solution of sodium chloride, unless the cells were resuspended in citrate or oxalate or a trace of citrated or oxalated plasma was added. Autohemagglutination of this type, the authors warn, may lead to errors in blood grouping unless the cells are washed in saline solution or the tests are carried out at body temperature.

Raynaud's Syndrome with Spontaneous Cold Hemagglutination.—Bemans and Feasby report 2 cases of Raynaud's syndrome in which autohemagglutination due to cold, in addition to angiospasm, may have been a causative factor. It is recognized that persons with one form of hypersensitivity often show other forms and it seems probable to the authors that in their 2 patients hypersensitivity to cold played a part in producing the agglutination and the Raynaud's syndrome, in the latter the arteriolar musculature would be the sensitive tissue.

*Study on Effects of War Conditions on Group of Pneumothorax Treated Patients J Kellermann—p 212

Effect of War on Pneumothorax Treated Patients.—Kellermann states that war has adversely affected the 33 patients who had pneumothorax refills during the first eighteen months of the war. A comparison of these 33 patients with 25 similar patients who had their refills before the outbreak of hostilities shows no appreciable change in the clinical condition of the 33 patients. The 33 patients lost weight or failed to gain weight. The loss or failure to gain weight was not due to food rationing but to the extrinsic factors of anxiety, excitement resulting from the military situation and loss of sleep owing to the prolonged and intensive aerial activity.

*Origin of Acute Anterior Poliomyelitis. C. Preioni.—p. 676.

Origin of Acute Anterior Poliomyelitis.—According to Preioni the mode of transmission of the virus of acute anterior poliomyelitis has not been definitely determined. The author observed two atypical and one typical case of the disease in a group of children with no contacts. The children lived on a farm in which, as well as in the large surrounding zone, no cases of the disease have been observed for the last four years. They had not been away from the farm for several months nor had they had visitors. All the animals on the farm and its surroundings were well. However, an epidemic of an infection had occurred one month before in the chickens and turkeys of the farm. The clinical picture of the infection in the birds resembled that of an acute or hyperacute anterior poliomyelitis. The animals exhibited a febrile condition and lay on the ground. Some died within three or four days; in others paralysis of the extremities developed after four or five days of the disease. The legs were more paralyzed than the wings. After about one week the birds began to improve, to eat and to move about. Paralysis regressed more or less slowly up to almost a complete disappearance in the birds with a moderate infection but not in those with an acute infection in which the sequels were permanent. One month after the occurrence of the infection one recovered turkey and one recovered hen were separately put into two different places with a normal turkey and a normal rooster which were brought from farms in which the epidemic did not occur. The newcomers got the infection and died. Two months after the occurrence of the infection two other recovered animals were put separately in contact with normal birds from localities free from the epidemic. Not one of the newcomers contracted the disease. A paralytic but otherwise healthy hen with complete paralysis of the legs was killed two months after the infection. The brain and spinal cord were normal on macroscopic examination. The brain, cerebellum and the pons were also normal in microscopic sections. The lumbar segment of the spinal cord and its corresponding spinal ganglions were the seat of a toxic infection with anatomicopathologic changes resembling those of acute anterior poliomyelitis in children. The author believes that the virus which causes acute anterior poliomyelitis is neurotropic. It is transmitted from chickens to children by the chicken louse (*Dismansium avis*) imported to the cities with the eggs and on the feathers of the birds. The increased incidence and virulence of acute anterior poliomyelitis during spring and summer seems to depend on the fact that cold weather diminishes the activity of the chicken louse and the virulence of the virus it carries.

*Granular Changes in Leukocytes in Connection with Surgical Operations. K. Boman.—p. 432.

Subungual Neoplasms. S. B. Rasmussen.—p. 441.

Total Extirpation of Patella.—Friberg reviews the literature on complete extirpation of the patella and reports observations on 30 patients, 2 of whom underwent bilateral operation. Patellar chondromalacia was the cause of the operation in the greatest number of cases (23); in the other cases patellar extirpation was performed to repair complications after patellar or femoral fractures. In 26 cases the quadriceps tendon was sutured to the patellar ligament. The time of observation after the operation varied from twelve to sixty months; the average was twenty-one months. In 13 patients (40.6 per cent) the operation resulted in a knee joint that was entirely free from symptoms and which could stand severe strains in work and sports without fatigue; 14 other patients (43.8 per cent) were free from symptoms as far as ordinary exertion was concerned but complained of insufficient strength under greater strain and of want of stability when walking on uneven ground, hitting

the foot or stumbling. Nevertheless, the latter patients considered themselves much improved by the operation. Thus the operation resulted in an adequately functioning knee joint in 84 per cent of the cases. Suturing of the quadriceps tendon to the patellar ligament produced a good anterior contour of the knee joint. There was complete extension in all the joints in which the tendon had been sutured and in four of the six without such suture. There were no signs of arthritis deformans, but the elapsed time was too short for final evaluation in this respect. Slight calcified deposits were observed in 26 cases at the site of the patella; in 2 cases they were considerable and gave rise to symptoms. The author recommends complete extirpation in cases of recent splintered fractures and of certain simple fractures of the patella.

Transduodenal Choledocholithotomy.—Brattström reports 8 cases of transduodenal choledocholithotomy in which the operation showed good results on a follow-up. This method gives a better survey and is associated with less risk than the retroduodenal method. The technic is described. In the presence of signs of an ascending infection of the bile passages, of internal biliary fistulas or of insufficiency of Oddi's sphincter, the author recommends gastric resection according to Finsterer-Polya.

Granular Changes in Leukocytes in Surgical Operations.—Boman points out that in healthy persons granules demonstrated by the same method show relatively slight deviations from a certain norm. Hammar in 1912 was able to show by means of vital staining with brilliant cresyl blue that the granules of the neutrophil leukocytes change in number and size during morbid conditions and that they increase in number in infectious diseases. These observations were recently confirmed by Hedenius, who found that the granules increase in exophthalmic goiter and that they decrease in chronic polyarthritis. Hedenius employed the metachromatic dye toluidine blue for staining. Using the staining method of Hedenius, Boman made studies on patients in a surgical department. Investigating granular changes during and after operations, he dissolved solid toluidine blue in a 3.8 per cent citrate solution so as to obtain a 0.02 per cent staining solution. Blood samples were taken in the same way and with the same proportion between blood and staining fluid as for a sedimentation test. The glass tube containing the sample was sealed with a rubber stopper and placed for thirty minutes in a thermostat at 37 C. During this time "storage" took place, so that the granules appeared more and more distinctly. After removal of the tube from the thermostat a smear was made which was ready for microscopic examination as soon as it had dried in the air. The author observed a decrease in the number of granules in the neutrophil leukocytes during operation, after severe trauma and before death.

*Value of Examination of Spinal Fluid in Diagnosis of Intracranial Tumors. Karen Bligaard.—p. 1286.

Treatment of Lipid Nephrosis with Potassium Nitrate. H. Kjaergaard.—p. 1289.

Value of Examination of Spinal Fluid in Diagnosis of Intracranial Tumors.—Bligaard reports that examination of the spinal fluid of 400 patients with verified intracranial tumors showed increased protein content and increased pressure in at least three fourths of the patients, with little or no increase in cells, but says that the examination is of almost no practical value in the diagnosis of intracranial tumors, as the increase in cells and protein is irregular and slight and such values may also appear in other diseases in and outside the central nervous system. Constant, well defined increase in the protein content is seen only in basal meningioma, papilloma in the fourth ventricle and acoustic neuroma; here, however, the diagnosis is almost always assured by the clinical examination and symptoms of increased cranial pressure, which contraindicates lumbar puncture.

Book Notices

Training and Efficiency. [An Experiment in Physical and Economic Rehabilitation.] By E. Jokl, E. H. Cluver, C. Goedvold and T. W. de Jongh. Boards. Pp. 188, with 46 illustrations. Johannesburg: South African Institute for Medical Research, 1941.

This is an elaborate report on another series of investigations on health and efficiency of the South African Institute for Medical Research. It gives a statistical statement of the improvement in physical fitness of a group of thirty-two special service recruits between 16 and 31 years of age. They had been unemployed, and their posture, general bearing and nutrition were poor. They were given good living conditions, strict discipline, and three hours of physical training a day. The whole procedure is roughly comparable to our CCC camp activities. The purpose of a six months course of training was physical, economic and social rehabilitation. Physical measurements and tests were taken before and after. They included weight, height, posture, trunk length, biacromial diameter, chest girth and diameter. All are tested by a 100 yard dash and a 3 mile run before and after the period. This is not as strenuous as it might appear to be, for several took twenty-six minutes to cover the distance. Only two made better time than twenty minutes in the first test, but nine did so after training. Physiologic tests were centered on respiration and circulation. Breath holding, a standard test for British civil aviators, of whom sixty-nine seconds is required, improved in the trainees from twenty-nine and thirty-nine one hundredths seconds to sixty-eight and fifty-two one hundredths. The respiratory rate after exercise changed little, but the first exercise decline of vital capacity "strikingly decreased." Pulse rates improved; i. e., they were slower after the period of training, changing from seventy-three and fifteen one hundredths to sixty-three and twenty one hundredths. The reaction rise of pulse rate to a standard exercise diminished to the twelfth week in training, but no improvement resulted afterward. The authors report that blood pressure readings at rest showed "an astounding lack of change during the whole period of training." They did not take blood pressure in both positions, standing and lying, as in our standard (Crampton and Schneider) tests of circulatory efficiency. Nor were exercise tolerance tests emphasized, but much prominence was given to blood pressure response to respiratory efforts. Posture, weight and athletic performance improved. The improvement was greater in all particulars in those who were substandard in the preliminary tests. They are of the opinion that "preparing the soldier so that both his fitness for life and his efficiency for battle are on the highest possible level is the supreme demand of the moment." They state that "the standard of physical fitness of a considerable percentage of men in this country is lamentably low."

This is an unusually elaborate intensive study of the effect of six months' training of thirty-two underprivileged young men. The conclusions given, however, rest on a broader base. The authors Cluver and Jokl refer to their earlier investigation (1940) indicating a similar condition among twenty thousand school children. The authors refer also to Jokl's experiment of one hour of physical training a day given to two thousand five hundred trainees in the industrial training field. There was an improvement in health, discipline and working efficiency. They point to the need of highly competent instructors. On the basis of the results of several investigations they recommend a program of fitness testing and training for all men in the population. The report closes with the following:

We cannot close our eyes to the fact that an astoundingly large number of individuals will not seek, out of their own initiative, ways and means to develop and educate themselves to the optimum of their potential abilities. For this reason we have come to the conclusion that it is necessary to introduce some system of compulsion under which the state would take charge of young citizens who are, for any reason, unable or unwilling to carry their weight in the economic life of the community.

In suggesting the introduction of compulsion into our democratic society, we feel that we have to anticipate the argument that we are interfering with "individual initiative." We wish to say, however, that our plan to advocate the use of "reasonable compulsion" is the direct result of our observation of individual initiative being lacking in a large number of people. To allow the present state of affairs to con-

tinue would mean to invite conditions still more disastrous than those which we are witnessing at present.

Who possesses initiative? Only a small percentage of the people; just enough, we hope, to elaborate, organize and control schemes of the type we have in mind. On the other hand, we are convinced that our scheme will introduce into society a new element of vigor and action.

Resuscitation Equipment, Organization, Training and Procedures. By Command of the Army Council. Great Britain War Office Publications No. 5120. Paper. Price, 25 cents; 9d. Pp. 56, with 17 illustrations. New York: British Library of Information; London: His Majesty's Stationery Office, 1941.

The American reader who has become accustomed to regard resuscitation as synonymous with artificial respiration will be surprised to find that this pamphlet deals almost exclusively with transfusion. Of the fifty-two pages devoted to the text, three pages refer to oxygen therapy merely as a complementary measure. The purpose of this pamphlet, as stated, is to present recommendations for the training of a special officer at each military hospital, general hospital and casualty clearing station as well as field ambulances in the etiology, pathology and treatment of secondary (synonyms traumatic, hemorrhagic, wound) shock. Since Webster's Dictionary refers to resuscitation as . . . "to revive, revivify or as to resuscitate from drowning," it would appear that the British use of the word is entirely correct and for that matter so is ours. The broader English use of this terminology may, however, serve as a useful integrator of present closely related but dissociated activities. The pamphlet has a strong appeal for the American physician because of the fact that it has been prepared from "experience gained at Dunkirk and from air raids in 1940." It immediately creates the impression of a reality which we may ourselves soon face. The text is concise, clear and enriched with all necessary detail. The matter is divided into two sections: 1. General principles, including advantages of a resuscitation ward, training of nurses and orderlies, duties of the resuscitation officer, equipment, supplies and communications. 2. Notes concerning procedures, equipment and materials used in resuscitative work. This section includes the taking of blood, transfusion reactions and care of equipment. Practical suggestions are given relating to hemostasis, splints, the administration of oxygen, morphine, chemotherapy and refrigeration. The text is illustrated with numerous halftones and helpful drawings. The practical value of this carefully prepared pamphlet to the American physician at this moment of emergency can scarcely be overestimated. It deserves careful study and close imitation because of the simplicity of its approach. It serves as a substantial foundation on which resuscitation, as we are accustomed to think of the term, may subsequently be added.

Tratamento da lepra à luz de novas idéias. Por el Dr. J. M. Gomes, assistente-clínico do Instituto de Higiene, Universidade de São Paulo. Paper. Pp. 189, with illustrations. São Paulo: Empresa Gráfica da "Revista dos Tribunais," 1941.

In this volume the author describes a new specific for the treatment of leprosy. This time it is the vitamins, particularly vitamin A in the form of "Alfon." In the light of the recent discoveries on the mode of action of the vitamins, the author points out their benevolent possibilities in the treatment of a chronic infectious disease such as leprosy. It is stressed that the Hansen bacillus is not the only cause of this disease but that there is a predisposing factor in the form of a dietary deficiency.

The author has studied the morphology of *Mycobacterium leprae* in its human parasitism. He claims to have discovered that there are evolutionary and involutionary phases in its life cycle. The evolutionary phase is virus, homogenous acid-fast bacillus, granular acid-fast bacillus, acid-fast granulation and virus. The involutionary phase comprises virus, homogenous acid-fast bacillus, fragmentary acid-fast bacillus, acid-sensitive bacillus, acid-sensitive granulation and destruction.

"Alfon," the new specific, is the trade name of a product manufactured by the "Laboratorios Farmaceuticos Reunidos" of São Paulo, Brazil. It is stated to be a 2 per cent colloidal suspension of carotenoids in physiologic solution. A carotenoid is a previtamin A obtained from plant life. After injection, carotenoids are said to be transformed into vitamin A through fermentation, which takes place in the liver.

As a foundation for this new form of therapy the author discusses in detail the similarity between the early manifestations of leprosy and those of avitaminosis A. Vitamin A is spoken of as the great anti-infection vitamin, the stimulator of phagocytosis and the protector of epithelium. It is considered the essential vitamin for the preservation and proper functioning of the ocular apparatus. By animal experimentations it is said that it has been shown that a lack of this vitamin leads to a demyelination of the peripheral nerves. Leprosy, the author states, is most prevalent in localities where the native food is poor in vitamin A. The potentiality for good of vitamin A in leprosy is pointed out in that it is the epithelium, the peripheral nerves and the ocular tissues which are most vulnerable in this disease.

"Alfon" is claimed to have two modes of action in leprosy. The one, a biotrophic action on the germs, is a specific action, whereby the evolution of *M. leprae* is hastened through its various phases to its final degeneration stage and disappearance from the lesion. The other, a nonspecific action, is a stimulation of the body tissues' defensive mechanism against infections in general.

The final chapter of the book deals with case reports. Of 400 cases treated with Alfon, only 238 are reviewed because of adverse circumstances in the others. The period of observation is eight to nine months, which is short for such a chronic disease. The data presented are not convincing as to the permanence of the improvements claimed to have occurred. There have been some adverse reports in the medical literature on the use of Alfon in leprosy. The most objectionable feature of this product has been the manner in which it has been extensively advertised in the public press of Brazil as a true specific. At the National Leprosarium, Carville, La., no favorable results were noted in 10 cases of leprosy after ten months of treatment. The best that can be said for vitamin therapy in general is that it is still in its experimental stage.

Leaders of Medicine: Biographical Sketches of Outstanding American and European Physicians. By Solomon R. Kagan, M.D. Cloth. Price, \$3. Pp. 176, with 4 portraits. Boston: Medico-Historical Press, 1941.

This small book comprises fairly extensive notes on the careers of twelve leaders of medicine: Jacob Henle, Rudolf Virchow, Silas Weir Mitchell, Abraham Jacobi, Sir Thomas Clifford Allbutt, Jacob Da Silva Solis-Cohen, John Shaw Billings, Julius Cohnheim, Carl Weigert, Sir William Osler, William Henry Welch and Paul Ehrlich. These reviews are interesting, instructive and well written, showing perhaps the influence of the late Fielding H. Garrison, under whose inspiration the volume was written. The timeliness of certain portions of the book is apparent in a quotation from a letter of William Osler written in Berlin in 1884, who said "Should another Moses arise and preach a Semitic exodus from Germany, and should he prevail, they would leave the land impoverished far more than was ancient Egypt by the loss of the 'jewels of gold and jewels of silver' of which the people were 'spoiled.' To say nothing of the material wealth, enough to buy Palestine over and over again, there is not a profession which would not suffer the serious loss of many of its most brilliant ornaments, and in none more so than our own." A few of the more important historical statements in this book have been condensed and used in the Student Section of *THE JOURNAL* in the column "Do You Know What Physician—" Perhaps the success of this venture will encourage the author to go further into the field of medical history.

The Early Treatment of War Wounds. By William Anderson, O.B.E., M.B., Ch.B., Surgeon and Lecturer in Surgery, Aberdeen Royal Infirmary, Aberdeen. Oxford War Manuals. General Editor: The Rt. Hon. Lord Horder, G.C.V.O. Cloth. Price, \$1.50. Pp. 96, with 12 illustrations. New York & London: Oxford University Press, 1941.

This small "Oxford War Manual" is in reality a summary of the experiences of the author in World War I; as stated in the preface, he hopes that a record of the failures and successes in the treatment of the wounded will act as a starting point for the great advances which he is confident will be achieved during the present struggle. The first part of the first chapter is a masterful statement of the general principles for the care of the war wounded and should be read by every medical officer. The paragraphs on splinting in fractures are likewise excellent. Over half the manual, however, does not deal, as indicated in

the title, with the early treatment of war wounds but with the later operative procedures. The "present struggle" has already gone two years, which to the reviewer seems long enough to include in a manual of this kind some of the "great advances" which have already been achieved. For example, a sufficient experience has accumulated, certainly as judged by the many English reports, establishing the value of the sulfonamide drugs both in the prevention and in the treatment of war wound infections. The use of tetanus toxoid has also been extensive enough to commend it in the prophylaxis of lockjaw. The treatment of compound fractures has been so improved during recent years as to warrant inclusion in a current war manual. Plasma, liquid and dry, also deserves wide consideration on the basis of contemporary experiences. These and other topics, barely mentioned in the present work, could with profit be added to or incorporated with the experiences of twenty-five years ago. These experiences, while basic and valuable, seem in certain cases at least as outmoded as a model T Ford.

Effective Living. By C. E. Turner, A.M., Sc.D., Dr.P.H., Professor of Biology and Public Health, Massachusetts Institute of Technology, Cambridge, and Elizabeth McHose, B.S., M.A., Director of Physical Education for Girls, Senior High School, Reading, Pennsylvania. Cloth. Price, \$1.90. Pp. 432, with 164 illustrations. St. Louis: C. V. Mosby Company, 1941.

This is an excellent volume dealing with the problem of healthful living and how it may be attained. Part 1 deals with the individual's mode and manner of living. It discusses exercise, the mechanical use of the body, care of the skin, mental hygiene and food and gives adequate information on the vital organs. It does not go into minute detail in describing the respiratory system, the circulatory system and the excretory system but presents in an interesting way sufficient information on anatomy and physiology for most lay readers. In part II the authors discuss effective living in the family. Here healthful living conditions in the home are discussed, as well as the health of the family group. The chapter on becoming good ancestors will be particularly useful to the reader. Part III deals with effective living in the community. This part discusses sanitation, the various health agencies and their programs, as well as information on the prevention of communicable disease and the lowering of the death rate. Of particular value is the self-checking chart at the end of each subject and also the lists of problems and activities.

Las funciones digestivas en el organismo tuberculoso (estudio clínico y coprológico). Tesis de doctorado presentada por Juan Antonio Tabanera. Universidad nacional de Buenos Aires, Facultad de ciencias médicas, Acta No. 5346. Paper. Pp. 153, with 15 illustrations. Buenos Aires, 1940.

The author selected the subject of functions of digestion in tuberculous persons for his doctoral thesis. The clinical and coprologic study is based on observations of patients of his personal clientele. The chapters of the book cover the following topics: 1. Physiology of digestive tract from mouth to rectum. 2. Constituents of food and chemical transformation of food and alimentary bolus during digestion. 3, 4 and 5. Macroscopic and microscopic aspects, chemical constituents, chemical reactions and bacteriology of normal feces and of feces of patients with pulmonary tuberculosis, alone or complicated by intestinal tuberculosis. 6. Coprology in diagnosis of intestinal tuberculosis. 7. Clinical aspects and course of nontuberculous intestinal inflammation, colitis, intestinal ulceration and intestinal tuberculosis; tests for differential diagnosis, especially the catalase test. 8. Diet in intestinal tuberculosis, in accordance to location of tuberculous lesions in a given intestinal segment; also importance of vitamins in diet and in therapy of intestinal tuberculosis. The book ends with three pages of bibliography.

Medico-Legal Law Brief in Relation to Malpractice Suits with Citations. By John Ralph Ballinger, B.S., M.D., Chairman of the Medico-Legal Committee of the Illinois State Medical Society and of the Chicago Medical Society. Paper. No pagination. Chicago: The Author, 1941.

The author of this small brochure has been chairman of the Medico-Legal Committee of the Illinois State Medical Society and of the Chicago Medical Society for twenty-eight years and here presents, in brief form, comments on the nature of the complaints that have been filed by patients against members of the medical profession in Illinois, with citations to court decisions in point.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

VITAMINS AND RHEUMATOID ARTHRITIS

To the Editor—What is the present status of vitamin B therapy in arthritis and allied conditions? Edward Suckle, M.D., Coatesville, Pa.

To the Editor—Recently the treatment of chronic arthritis with high doses of vitamin D has been advocated. European publications state that the administration of high doses of vitamin D over a prolonged period is liable to produce irreversible arteriosclerotic changes. What is known on this subject? Lothor Luft, M.D., New York.

ANSWER—A deficiency of almost every one of the vitamins has been regarded as the cause of rheumatoid arthritis. A deficiency of vitamin B was first blamed by Fletcher in 1922, then of vitamin D by Dreyer and Reed in 1935 and a little later of vitamin C by Rinehart in 1935. More recently deficiencies of vitamins A and E in rheumatic patients have been studied. Such is the current frenzy of the layman for vitamins that rheumatic patients are pestering their physicians for the "antirheumatism vitamin" and they feel badly neglected unless some vitamin is prescribed.

VITAMIN A

Deficiencies of vitamin A in the plasma were noted by Race in 1937 among patients who had rheumatoid arthritis. This observation was confirmed by Hall, Bayles and Soutter in 1940, who suggested that these deficiencies might be responsible for the supposed susceptibility of rheumatic patients to infections of the upper part of the respiratory tract. The administration of vitamin A concentrates readily corrects the plasma deficiencies but does not improve the condition of the joints in rheumatoid arthritis (Monroe, Hall, Bayles and Soutter).

VITAMIN B COMPLEX

In 1922 and later years Fletcher suggested that certain features of rheumatoid arthritis might be related to a deficiency of vitamin B. In rheumatoid arthritis certain of the symptoms of thiamine hydrochloride (vitamin B₁) deficiency are sometimes present (weakness, anorexia, muscular atrophy, reduced dextrose tolerance, abnormalities of size and position of colon) but others are absent (polyneuritis, lymphopenia, excess lactic acid). Fletcher and others were able to produce atonic bowels in rats given diets deficient in vitamin B but no definite arthritis resulted. The diets of the patients of Sherwood and Thomson suffering from rheumatoid arthritis were rarely deficient in vitamin B, and neuritis was extremely rare. The administration of vitamins B₁ and B₂ has not produced any notable effect on arthritic patients. For these reasons most workers do not regard rheumatoid arthritis as a B avitaminosis (Race, Steinberg, 1936).

Sherwood and Thomson in 1939 noted that the home diets of their patients who had rheumatoid arthritis were commonly deficient in riboflavin (vitamin G), but no other clinical or therapeutic studies have been made.

Disappointed in their search for germs as the cause of rheumatoid arthritis and in the results of removal of foci of infection and administration of vaccines, physicians now are following the trend of the times and seeking evidence for an antirheumatic vitamin. Such a vitamin has not been discovered so far. Patients who have rheumatoid arthritis, like those who have many other diseases, often present subnormal amounts of various vitamins in their plasma, but these deficiencies are not specific for rheumatoid arthritis nor are they of proved etiologic significance. Like normal persons, arthritic patients should insure for themselves an adequate daily quota of vitamins but, as some one has said aptly, these should be bought at the grocery store, not at the drug store.

ASCORBIC ACID (VITAMIN C)

In 1935 Rinehart reported that subacute or chronic vitamin C deficiency produced in guinea pigs an arthropathy which he believed was somewhat similar to rheumatoid arthritis. Some of his patients suffering from rheumatoid arthritis presented evidence of vitamin C deficiency. Therefore Rinehart suggested that vitamin C deficiency might be an etiologic factor in rheumatoid arthritis. He and others (Rinehart, Greenberg and Baker) later reported low concentrations of ascorbic acid in the plasma in rheumatoid arthritis. That such a deficiency exists has been

noted since by others also, and this deficiency of vitamin C in the plasma may exist whether the patient's diet is or is not deficient in the vitamin. However, scurvy is not present. To Rinehart and his colleagues in 1938 the results in some cases of rheumatoid arthritis in which ascorbic acid was given were "distinctly encouraging," but others who have administered vitamin C in large amounts parenterally and orally have not observed any notable effects on the joints, although the vitamin deficiencies in the plasma were corrected readily (Holbrook and Hill, Race, Jacques).

VITAMIN D

Two arthritic patients to whom Dreyer and Reed in 1935 gave massive doses of vitamin D for their hay fever noted improvement in their joints. Therefore Dreyer and Reed gave similar large doses to other arthritic patients with reported improvement. Diminution of pain and an improved sense of well-being presumably were noted. But toxic symptoms (nausea, polyuria, polydipsia, vomiting) fairly frequently appeared. Later Reed adopted a working hypothesis that in "arthritis" there may be an obscure disturbance of calcium metabolism which vitamin D somehow "stabilizes." But many workers have failed to demonstrate any abnormality of the metabolism of calcium in rheumatoid arthritis, and Reed admitted that patients receiving massive doses of vitamin D did not exhibit any consistent changes in the concentration of calcium or phosphorus in the blood and urine. The most voluble proponent of vitamin D therapy has been Farley, who repeatedly has reported "remarkable results" in almost every case of "arthritis" so treated. Farley has insisted that vitamin D as prepared by the Whittier process (citron) is more effective and less toxic than vitamin D preparations prepared otherwise. Snyder and Squires in their paper of 1940 appeared to share this view, but this contention remains unproved and the further report of Farley in 1941 continued to exhibit intemperate enthusiasm and a lack of critical judgment.

Other preparations of vitamin D have been given to arthritic patients by several workers (Cohen, Abrams and Bauer, Steinberg, 1938, Muether), who have not noted any striking results; there has been occasional subjective improvement but little or no objective improvement and no significant reduction in sedimentation rates. The use of massive doses of vitamin D in treatment of patients suffering from chronic arthritis therefore has been called "irrational" (Ishmael and McBride) or even "dangerous" (Cohen). The Council on Pharmacy and Chemistry of the American Medical Association in 1937 did not accept vitamin D as an approved remedy for any form of arthritis, contending that there is no evidence that the doses used have been nontoxic or effective. The Council did not find any scientific evidence to support the claims made and deprecated the unwarranted exploitation of these products by certain manufacturers. Despite the Council's report, certain preparations of vitamin D, notably Ertron, continue to be advertised vigorously, one might say offensively in view of the glowing terms applied to them. These preparations are rather expensive when their use is long continued, and they do not seem to be worth the money even though their long continued use is probably not as dangerous as some writers have suggested.

VITAMIN E

To date vitamin E has not been linked with rheumatoid arthritis, but Steinberg suggested in 1941 that primary fibrositis may represent not an infectious process but a metabolic disturbance, perhaps a deficiency of vitamin E. However, confirmatory evidence is obviously indicated before the therapeutic possibility of vitamin E in this field can be evaluated.

TREATMENT OF LATE SYPHILIS IN PATIENT WITH POOR VEINS

To the Editor:—A woman aged 50, weighing 250 pounds (113 Kg.), has late syphilis. It has been about twenty-five years since the initial lesion. The diagnosis is syphilitic aortitis. The patient's veins cannot be isolated for intravenous medication. 1. What is the value of sulfarsphenamine? 2. What is the relative value of sulfarsphenamine as compared with neosarsphenamine? 3. What are the dosage and frequency of administration? Is it painful? 4. What is the usefulness of iodides, mercury and bismuth compounds in such a case? 5. What course of treatment would you recommend?

Maxwell Herschleder, M.D., Gary, Ind.

ANSWER.—1. Sulfarsphenamine should not be used for adults because of the risk of serious reactions, particularly postarsenical dermatitis, blood dyscrasias and encephalitis. Bismarsen is a much safer arsenical drug for use in these circumstances.

2. With adequate dosage and spacing of dosage, bismarsen may be considered under the circumstances to be the equivalent of neosarsphenamine.

3. The usual dose is 0.2 Gm. given twice weekly. There is often mild to moderate pain after the intramuscular injection of bismarsen, which may be minimized by proper technic.

4. Either or both heavy metals and potassium iodide may be used in a case such as that described.

5. Treatment may begin with twelve weekly intramuscular injections of bismuth subsalicylate in oil, each 0.2 Gm., combined with the simultaneous administration of potassium iodide by mouth in a dose of 1 to 2 Gm. three times daily. This may be followed by a course of twenty intramuscular injections of bismarsen, the first dose of which should not exceed 0.05 Gm. and subsequent doses of 0.1 to 0.2 Gm., depending on the type and extent of aortic involvement. If the patient has uncomplicated syphilitic aortitis without evidence of cardiac embarrassment or congestive heart failure, the average dose of 0.2 Gm. twice weekly may be used. If, on the other hand, either sacular aneurysm or aortic regurgitation is present or if the patient has beginning signs of myocardial failure, the dose should not exceed 0.1 Gm. Thereafter treatment should be kept up for a minimum period of two years with courses of bismuth subsalicylate alternating with courses of bismarsen. If it is desired to substitute mercury for bismuth subsalicylate, intramuscular injections of any mercurial product should not be used, but instead the drug should be given by inunction.

It goes without saying that this antisyphilitic treatment should be accompanied by appropriate general medical care, including weight reduction.

Further details as to the treatment of cardiovascular syphilis may be found in chapter 20 of Stokes, J. H.: *Modern Clinical Syphilology*, Philadelphia, W. B. Saunders Company, 1934, or in chapter 18 of Moore, J. E.: *Modern Treatment of Syphilis*, Springfield, Ill., C. C. Thomas, 1941.

VACCINES FOR CHRONIC SINUSITIS

To the Editor:—What is the consensus among otolaryngologists as to the efficacy of vaccines in the clearing of chronic sphenoidal sinusitis? Which is preferred, stock or autogenous? What is the usual method of employment of the vaccine?

M.D., Pennsylvania.

ANSWER.—It is impossible to answer categorically as to the efficacy of vaccines in chronic sinusitis. In general it may be fairly said that many or most rhinologists are dubious about their value in these conditions. There is, however, considerable evidence on the other side which must be accepted with respect until the question is more positively settled.

For instance, Walsh in experimental animals instilled bacterial antigen intranasally and found a "mobilization of leukocytes and macrophages in the subepithelial areas, conditions which elsewhere in the body have been shown to be associated with increased resistance to infection." Furthermore, there was produced by this instillation specific agglutinins in the nasal mucosa, the blood serum and various organs of the body. Walsh worked with *Salmonella paratyphi B* and *Eberthella typhosa*. Others, notably Linton, obtained experimentally similar results using virulent strains of streptococci. Walsh made a vaccine com-

posed of various strains of bacteria obtained from the nasal passages of patients, which was to be instilled in the noses of patients desiring relief from colds and the like.

Similar results have been obtained in patients by use of a vaccine composed of numerous strains of organisms recovered from the nasal passages of persons suffering from infections. Gundrum treated 500 patients suffering from chronic sinusitis. He used stock bacterial antigens made after Besredka's method and instilled it after the displacement method of Proetz. A large number of patients reported permanent improvement.

Putting aside the various claims for and against the use of vaccines, it may be agreed that results must depend in large degree on the amount of mucous membrane and even bone damage present in each individual case.

If an autogenous vaccine is used it must be reasonably certain that the offending organisms will appear in the culture and vaccine and not be overshadowed or overgrown by others with no etiologic significance. In this respect stock vaccines may be superior because they contain numerous strains of possible offenders.

Vaccines may be employed by injection or instilled in the nose with a dropper or used after the displacement method of Proetz. Information available to date is too indefinite to permit of positive recommendations.

MANAGEMENT OF FRACTURED TEETH AND ALVEOLAR PROCESS

To the Editor:—A patient aged 60 had a simple fracture of the upper alveolar process of the upper jaw with a fracture of the roots of two incisors. The fracture was reduced within five minutes. The teeth were not extracted. They were replaced as near as possible to their normal position. Some of four upper incisors were pulled downward but were replaced in os nearly normal a position as possible. The teeth occl on a splint. Should the fractured teeth be extracted? If so, how soon if no complications develop? If one of the teeth was filled years ago and the filling did not reach the bottom of the cavity, should it be extracted? It is taken for granted that the nerve of the tooth was killed. When the root of a tooth is fractured should it be extracted? I am referring only to the teeth mentioned. The patient has chronic arthritis.

M.D., New Mexico.

ANSWER.—As a general rule, the preferable treatment of a patient such as that described is conservative, rather than immediate extraction of such fractured teeth, especially if the teeth can be utilized in the stabilization of the fractured bones. If complications arise, then the fractured teeth can be extracted as indicated. If the teeth can be utilized in immobilizing the fracture until it has healed there is less danger of loss of bone through infection and sequestration. It is important to conserve the bone and wait until such time as the problem resolves itself into a dental one. However, the clinical aspect of the patient should govern the treatment.

RELEASE OF TOURNIQUET

To the Editor:—Concerning the frequency of temporary release of a tourniquet applied for arterial hemorrhage, a lecturer to industrial classes in first aid tells me that the men like definite time, not a variable of from ten to twenty minutes as stated in various manuals. What would be the best definite time to give these men for such frequency?

Harold B. Osborn, M.D., Fillmore, Calif.

ANSWER.—In case a tourniquet is applied for the control of arterial hemorrhage, it is wise to release the tourniquet for a few minutes at thirty minute intervals. If the extremity is packed in ice, this time interval can be safely extended to one hour.

MULTIPLE LIPOMAS

To the Editor:—A man aged 26 has had numerous subcutaneous lipomas involving the limbs and the trunk for the last six years. These vary in size, number at least a hundred and are painless except when they are irritated at friction points. The general health is good, and there are no other abnormalities. Biopsy done under local anesthesia revealed these tumors to be labulated and encapsulated and to consist entirely of fat cells and connective tissue. The patient states that the tumors are increasing in number with time and in size as he gains weight. Is there any therapy besides excision that will help him?

Anthony E. Sukis, M.D., Chicago.

ANSWER.—There is no effective therapy other than excision for such lesions.

THE SPECIFIC GRAVITY OF HEALTHY MEN

BODY WEIGHT \div VOLUME AS AN INDEX
OF OBESITY

A. R. BEHNKE JR., M.D.
Lieutenant Commander, M. C., U. S. Navy

B. G. FEEN, M.D.
Lieutenant, M. C., U. S. Navy
AND

W. C. WELHAM, M.D.
Lieutenant, M. C., U. S. Navy
WASHINGTON, D. C.

The fundamental biologic determination of corporeal specific gravity, essentially a relationship between weight and unit volume, has been neglected in the modern classification of healthy persons. Stern¹ and Spivak² emphasized the value of the measurement of corporeal density, but their experimental data are not conclusive. Of especial interest is the relationship between specific gravity and the fat content of the body.

The presence of an indeterminate amount of excess adipose tissue renders difficult any precise computation, for example, of metabolic rate or dosage of drugs in terms of total body weight. The important consideration should be the weight of the lean body representing the active mass of protoplasm.

In this paper the data support the concept that the comparatively low specific gravity of fat makes the measurement of the specific gravity of the body mass valid for the estimation of fat content.

The comprehensive, statistical analysis of Boyd,³ however, covering seven hundred and eighty-seven values reported since 1906 does not permit a classification of individuals with respect to obesity. The analyzed results,³ moreover, obtained by different investigators elude comparison by reason of the unknown quantity of air present in the lungs when the measurements were made.

In the present investigation the values of specific gravity obtained on ninety-nine healthy naval men in the 20 to 40 year age group were corrected by determining the residual air volume. The results obtained permit the classification of individuals as to degree of obesity and serve as a single index of physical fitness to supplement the standard age-height-weight tables

which frequently lead to a designation of overweight for well developed men in contrast with a designation of normal weight for more obese individuals who fall into a lower weight group.

METHOD OF PROCEDURE

The essential measurement is that of body volume, which, based on Archimedes' principle, can be conveniently determined by the method of hydrostatic weighing, i. e. equivalent volume = weight in air — weight in water. The weight in water is determined by suspending a subject below the surface of the water on a line leading up to a spring scale graduated in ounces. A weighted lead belt maintains negative buoyancy for all types of persons.

Two weighings in water serve to check the accuracy of the procedure: one at the completion of maximum inspiration and the other at the end of maximum expiration.

The difference in weight obtained records hydrostatic displacement, which serves as a measure of vital capacity. This determination of vital capacity when corrected for the effect of the mean hydrostatic pressure on thoracic volume gives values comparable to those obtained by the standard method employing spirometry.

In the determination of residual air, the inhalation of a helium-oxygen mixture for a period of three minutes following maximal expiration brought about a removal of the residual nitrogen. The subsequent washing out during normal respiration of the previously inhaled helium with 50 liters of air or oxygen permitted an accurate computation of residual pulmonary volume comparable to unpublished results obtained by Willmon and Behnke using the nitrogen dilution method. Duplicate determinations usually gave values which differed by not more than 150 cc.

CIRCUMFERENTIAL MEASUREMENTS OF CHEST AND ABDOMEN

The circumferential measurements of the chest and the abdomen are subject to considerable variation unless special care is exercised. The values recorded were obtained usually in the midmorning, during quiet respiration and with the arms of the subject extended vertically. Under these circumstances errors arising from altered muscular tonus or voluntary retraction of the abdomen were minimized. The chest measurement was made at the level of the nipples, the abdominal measurement at the level of the umbilicus.

SOURCES OF ERROR

The greatest error arises from the determination of residual lung volume. If the variation in this measurement is of the order of 200 cc., values for specific gravity will be subject to an error of ± 0.003 .

The material in this article should be construed only as the personal opinion of the writers and not as representing the opinion of the Navy Department officially.

1. Stern, H.: Investigations on Corporeal Specific Gravity and on the Value of This Factor in Physical Diagnosis, *M. Rec.* 59: 204-207, 1901.
2. Spivak, C. D.: The Specific Gravity of the Human Body, *Arch. Int. Med.* 15: 628-642 (April) 1915.
3. Boyd, Edith: The Specific Gravity of the Human Body, *Human Biology* 5: 646-672 (Dec.) 1933.

Repeated determinations on the same individual permitting the use of a constant volume for residual air give values that agree to within 0.003.

A second error may arise from the presence of gas in the abdominal viscera. In an attempt to minimize this error, determinations were made in the morning on the fasting individual.

TABLE 1.—Example Illustrating the Method of Computing Specific Gravity

	Pounds	Kilograms
Weight of the body in air . . .	183 00	83 20
Weight in water, full inspiration . . .	14 20	6 45
Weight in water, complete expiration . . .	23 20	10 55
Vital capacity computed from the volume of water displaced . . . 4,090 cc		
Vital capacity by spirometric measurements . . . 4,150 cc		
Volume of residual air . . . 1,200 cc		
Weight of abdominal belt . . .	13 75	6 25
Corrections		
Gross weight in water . . .	23 20	10 55
Weight of belt . . .	13 75	6 25
Weight in water, not corrected for residual air . . .	9 45	4 30
Correction for residual air (1,200/453) . . .	2 65	1 20
Net weight in water . . .	12 10	5 50
$\text{Specific gravity} = \frac{\text{Weight}}{\text{Volume}} = \frac{183}{170.9} = 1.071$		

RESULTS OBTAINED

In table 4 are listed values obtained on ninety-nine healthy men in military service. From analysis of the data, two facts are apparent: 1. Specific gravity increases inversely in relation to weight. 2. The difference between abdominal and thoracic girth can be correlated with specific gravity.

In table 2 the values for residual air indicate that any error in the determinations will not appreciably alter the relative classification of the subjects with respect to specific gravity. It is apparent that the range of values for residual air is large so that any individual measurement of specific gravity must be accompanied by an actual determination of residual air. For groups of twenty or more men, however, when average values are compared, an arbitrary figure of 1,450 cc. for

TABLE 2.—Residual Air and Vital Capacity Values

Specific Gravity	Number of Men	Average Residual Air, Liters	Residual Air, Range	Average Vital Capacity, Liters	Vital Capacity, Range
1.020-1.029	2	1.315	1.312-1.317	4.350	4.100-4.600
1.030-1.039	2	1.357	1.200-1.513	4.125	4.100-4.150
1.040-1.049	4	1.131	0.850-1.486	4.675	3.700-5.000
1.050-1.059	20	1.525	1.060-2.398	4.888	3.575-6.000
1.060-1.069	23	1.179	0.707-1.643	4.757	3.975-6.095
1.070-1.079	27	1.504	0.858-2.650	4.820	3.875-6.200
1.080-1.089	14	1.379	0.706-2.126	5.003	4.400-5.750
1.090-1.099	7	1.730	1.098-2.204	5.085	4.250-5.970

residual pulmonary volume will not introduce an error greater than ± 0.003 in the computation of specific gravity.

In table 5 the ninety-nine subjects are divided into three groups on the basis of high, low and middle range values for specific gravity. In the low group are listed all values below 1.060, and in the high group are values above 1.074.

Table 3 indicates how the loss of 19.5 pounds of adipose tissue in one subject results in a change in specific gravity. The values for the weight in water

have been corrected for a residual air volume of 1,200 cc. One notes that a decrease in abdominal girth is followed by an increase in specific gravity.

COMMENT

Difference in Thoracic and Abdominal Girth as an Index of Corpulence.—Although variation in individual values except for the most obese subjects is considerable, the group values in relation to specific gravity show a definite trend according to table 4. The lean subjects on inspection possess the greater circumferential difference between chest and abdomen in comparison with the corresponding difference in fat men.

Body Weight and Specific Gravity.—The relationship between body weight and specific gravity (table 4) is not absolute but relative in the sense that for any selected group of homogeneous persons the heaviest men tend to have specific gravity values in the low range of the scale. The rather uniform decrease in average weight in relation to specific gravity is to be regarded as coincidental. Lean men, for example, weighing 200 pounds will have high specific gravity values in contrast with the measurements on fat men of the same weight.

The average weight, for example, of thirty-eight men in the high specific gravity group (table 5) was 148.7 pounds. In a separate series of determinations on exceptional athletes, presented in the second paper, a similar high value for specific gravity was associated

TABLE 3.—Individual Loss of Weight in Relation to Specific Gravity

Date	Specific Gravity	Weight				Circumference			
		In Air		In Water (Net)		Chest		Abdomen	
		Pounds	Kg.	Pounds	Kg.	Inches	Cm	Inches	Cm
3/12	1.056	202.5	92.0	10.8	4.9	38.5	97.8	35.2	89.4
7/1	1.060	194.5	88.4	11.0	5.0				
8/13	1.066	187.0	85.0	11.6	5.3	38.7	98.3	35.0	89.8
10/9	1.071	183.0	83.2	12.1	5.5	39.1	99.3	31.4	79.7

with an average weight of 200 pounds. These facts suggest a fundamental relationship between adiposity and specific gravity.

Specific Gravity and Obesity.—Corporeal density serves as an index of the amount of excess adipose tissue. In table 5 the average weight in water of the low specific gravity group was 9.4 pounds, corresponding to a specific gravity value of 1.056. The corresponding values for the high specific gravity group were 11.1 and 1.081. The difference in weight in air between the two groups is 27.3 pounds.

On the assumption that a loss of 27.3 pounds of body weight in air is associated with a gain of weight in water of 1.7 pounds (11.1—9.4), the specific gravity of the low group following this loss of weight will be raised from an initial value of 1.056 to 1.081.

Thus, for every pound of weight lost the weight of the body in water is increased 0.062 pound (1.7 ÷ 27.3). The specific gravity of the reduced tissues is therefore 0.94 (1 ÷ 1.062), or a value in accord with the specific gravity of adipose tissue.

The average difference in thoracic and abdominal measurements of 5.8 and 3.7 inches for the high and low groups respectively suggests that excess adipose tissue accounts essentially for the difference in values for specific gravity of the two groups.

Individual Loss in Weight (table 3).—A man placed on a restricted diet and engaging in systematic exercise

lost 19.5 pounds over a period of seven months. The net weight in water increased from 10.8 pounds to 12.1 pounds, although the corresponding weight in air decreased from 202.5 pounds to 183.0 pounds. Thus, for every pound of weight lost in air the weight in water increased 0.067 pound ($1.3 \div 19.5$). The specific gravity of the reduced tissue is therefore 0.937 ($1.000 \div 1.067$), or a value again in accord with the specific gravity of neutral fat.

The reduction in abdominal girth further suggests that the eliminated tissue was chiefly fat.

Specific Gravity and Composition of the Body.—Of all the constituents of the tissues of the body, fat and bone appear to be the chief determinants of the ultimate

on the specific gravity of blood and various other tissues according to Vierordt⁴ and Nadeshdin.⁵

With reference to the specific gravity of blood, eighty-one determinations made according to the method of Barbour and Hamilton on eighteen of the ninety-nine subjects reported on in this paper gave an average in agreement with the data of Stern¹ of 1.060, standard deviation 0.002.

The percentage of skeletal weight in relation to the body as a whole exclusive of excess adipose tissue may not be expected to vary more than 4 units. Corresponding to this variation of 4 units in the percentage of body weight attributed to bone is a fluctuation of specific gravity of 13 units (table 6).

† Excess adipose tissue.

values for specific gravity. In the comparison of the three groups (table 5) the difference between the average of the high and low values could best be attributed to a variation in adipose tissue. On the other hand, it is expected that the relative amount of bone may alter individual values within a limited range.

In table 6 hypothetical examples are presented to clarify the relationship between specific gravity and the composition of the body especially with respect to variation in the percentage of bone and fat.

For the purpose of our analysis the body may be viewed as comprising calcium salts representing 50 per cent of the weight of bone, essential or irreducible lipid substance, excess adipose tissue, and all other tissues of the body embracing chiefly muscle, organs, brain, skin and blood.

The specific gravity of the mineral substance of bone is of the order of 3.0, adipose tissue 0.94, and all other tissue 1.060. This last figure is an approximation based

on contrast with bone, the amount of excess fat is subject to wide variations and a value of 30 per cent of the total body weight is not unreasonable for obese persons. If a lean man weighing 140 pounds, for example, accumulates 60 pounds of adipose tissue, the corporeal specific gravity will be lowered from 1.082 to 1.035, representing a difference of 46 units.

Since the density of the mass of tissue exclusive of bone and fat is probably constant for healthy men, the amount of fat appears to be the main factor affecting the specific gravity of a person.

Our concepts with regard to the composition of the body can be summarized by the accompanying diagrams. A, for example, the volume of a lean body mass weigh-

4 Vierordt, H. Anatomische, physiologische und physikalische Daten und Tabellen, 3d rev. ed., Jena, Gustav Fischer, 1906

5. Nadeshdin, W. A.: Zur Untersuchung der Minderwertigkeit der Organe an Leichen, Deutsche Zeitschr. f. d. ges. gerichtl. Med. 18: 426-431, 1932

ing 200 pounds (90.9 Kg.), specific gravity 1.082, is divided into its components 1, 2 and 3.

In *B* the inner circle encompasses a mass similar to *A* in specific gravity and composition but differing in weight by 60 pounds (27.3 Kg.). The outer circle circumscribes an accumulation of 60 pounds (27.3 Kg.) of adipose tissue. The specific gravity of this 200 pound mass can be computed as 1.035, in contrast with the value of 1.082 for the mass represented by the inner circle.

The fundamental problem of the amount of variation of constituents 1 and 2 within the lean body mass remains to be determined. For the present the assumption is made that the percentage variation of these constituents based on body weight is small for lean men.

Excess fat therefore is viewed as the prime factor governing the level of specific gravity.

Precise measurements, however, of this excess fat will necessarily await a knowledge of the relative percentage variation of the weight of the skeleton in lean persons.

A represents the volume percentages of the three major specific gravity determinants of the body for a 200 pound, 90.9 Kg., lean man. The calculations were based on the following data: bone 10 per cent of body weight, specific gravity 1.60; essential fat 10 per cent, specific gravity 0.94; tissue 80 per cent, specific gravity 1.06. The volume percentages are therefore bone 6.8 per cent, essential fat 11.5 per cent, tissue volume 81.7 per cent. The specific gravity of this man would be 1.082. The solid inner circle in *B* represents the volume percentages for a 140 pound, 63.6 Kg., lean man. The volume percentages and specific gravity are the same as for the 200 pound (90.9 Kg.) lean man. The dotted outer circle represents the addition of 60 pounds of excess fat to the 140 pound lean man. The bone volume percentage is lowered to 4.5 per cent, the fat volume percentage is increased to 40.8 per cent and the tissue volume is reduced to 54.7 per cent in this man. Thus the specific gravity of the body is reduced to 1.035.

Of the anthropometric measurements, the chest diameters and height are expected to modify the values for specific gravity in persons possessing the same degree of obesity.

CONCLUSIONS

1. The fundamental biologic characteristic of corporeal density can be accurately measured usually within 0.004 unit by the method of hydrostatic weighing, provided a correction is made for the air in the lungs.
2. Values of specific gravity for healthy men ranging in age between 20 and 40 fall between 1.021 and 1.097.
3. Low values for specific gravity indicate obesity and, conversely, high values denote leanness.
4. Individual loss in weight through exercise and a restricted diet is associated with an increase in specific gravity.
5. Difference in the circumferential measurements of chest and abdomen serve as a criterion of obesity and can be correlated with specific gravity.
6. Variation in the percentage of bone in relation to body weight, excluding excess fat, is not expected to produce deviation of more than 0.013 units in comparable values.

THE SPECIFIC GRAVITY OF HEALTHY MEN

BODY WEIGHT ÷ VOLUME AND OTHER PHYSICAL CHARACTERISTICS OF EXCEPTIONAL ATHLETES AND OF NAVAL PERSONNEL

W. C. WELHAM, M.D.

Lieutenant, M. C., U. S. Navy
AND

A. R. BEHNKE JR., M.D.

Lieutenant Commander, M. C., U. S. Navy
WASHINGTON, D. C.

In the preceding paper Behnke, Feen and Welham¹ have emphasized the value of the specific gravity of the body as a whole as an index of obesity. In their investigations a high value of 1.081 was associated with an average weight of 148.7 pounds (67.6 Kg.), while the corresponding weight for a group having an average low value of 1.056 was 176 pounds (80 Kg.).

If obesity and not weight per se is the chief factor tending to produce low values for specific gravity, then conversely a group of heavy but lean men should possess a high average value for specific gravity.

It was of considerable interest, therefore, to make a study of professional football players, the majority of whom had been selected for "all American" football teams. Essentially it was found that, although the average weight of these men was 200 pounds (90.9 Kg.), the average specific gravity reached the high value of 1.080. For comparison with these data and those recorded in the preceding paper, additional measurements were made on seventy-five naval men.

According to standard height-weight tables the majority of the football players could be classified as unfit for military service and as not qualified as risks for first class insurance by reason of overweight. The data presented in this paper therefore support the concept that specific gravity or weight of tissue per unit volume gives a true index of proper weight and not the standard tables which interpret weight in relation to height.

These findings together with accurate measurements of thoracic and abdominal circumferences and diameters provide information as to the physical characteristics associated with rugged physique and unusual fitness.

METHODS EMPLOYED

The technic used to measure specific gravity has been described in the preceding paper.¹ The body weight both in air and in water was accurately recorded to within 30 Gm. Measurements were made on the athletes following a morning "workout" and prior to eating. Similar data were recorded on naval personnel usually in the mid morning.

The chest diameters, anteroposterior and lateral, were taken with broad branched calipers at the level of the nipple line and recorded at the mean between inspiration and expiration in accordance with instructions from Dr. Meš Hrdlička. For these measurements the subjects stood relaxed in the manner indicated in figure 2A, elbows held at an angle of 45 degrees from the body, and forearms and hands held in a position of dependent flexion.

The material in this article should be construed only as the personal opinion of the writers and not as representing the opinion of the Navy Department officially.

1. Behnke, A. R., Jr.; Feen, B. G., and Welham, W. C.: The Specific Gravity of Healthy Men, this issue, p. 495

The body height was recorded with the subject standing erect, his back in contact with a vertical meter stick scale along which a wide sliding prong was used to touch the vertex of the head.

The circumference of the chest and of the abdomen was measured by means of a shellacked length of linen tape graduated in millimeters. For these measurements

as 200 pounds (90.9 Kg.), height as 72 inches (182.9 cm.), age as 25 years, circumference of the chest as 40 inches (101.6 cm.) and of the abdomen as 33 inches (83.8 cm.). As the weight increases in this group, values for specific gravity tend to decrease.

In table 2 corresponding data are presented from measurements obtained on seventy-five men in the naval

the subject stood erect and held his arms fully extended upward, the palmar areas of the hands in contact (fig 2B). This maneuver reduced to a minimum the influence of the pectoral musculature and fat.

The residual volume of the lungs was determined on all subjects by the helium dilution method.¹

RESULTS OBTAINED

In table 1 are listed the values obtained on the twenty-five exceptional athletes. The averages in whole numbers list specific gravity as 1.080, weight

as 200 pounds (90.9 Kg.), height as 72 inches (182.9 cm.), age as 25 years, circumference of the chest as 40 inches (101.6 cm.) and of the abdomen as 33 inches (83.8 cm.). As the weight increases in this group, values for specific gravity tend to decrease.

In table 2 the averages are given for naval personnel divided into three groups on the basis of high, middle and low values for specific gravity, i. e. above 1.074, 1.060 and 1.054 inclusive and below 1.060 respectively. For comparison, corresponding data are listed for the athletes.

The values for residual air showed the greatest range of variation in naval personnel compared with similar values for athletes. An average figure of 1,500 cc. for both groups is in close agreement with previous determinations.¹

CHEST AND ABDOMINAL MEASUREMENTS

The difference in circumference between chest and abdomen of 6.9 inches (17.5 cm.) for the athlete and of 6.8 inches (17.3 cm.) for the lean naval man is

Fig 1—The specific gravity of each subject is plotted on the ordinate against the ratio of weight to height for that subject on the abscissas. The dotted points represent values for naval personnel, and the circled dots represent two subjects falling on the same point. The crosses represent values for the athletes studied. The vertical line at a weight to height ratio of 2.65 represents the upper limit of the ratio allowable in selection of men for military duty. For the age group represented by this series, those to the right of the vertical line are considered not qualified as good risks for first class insurance by reason of overweight.

in accord with the conclusions that these types of men possess minimal adipose tissue. For the group having a low specific gravity of 1.051 (table 3) the corresponding difference is 4.5 inches (11.4 cm.).

Although individual variation in the circumferential difference is large, the group values correlate closely with specific gravity. Since these measurements are easy to obtain, their difference may serve as a good index of relative obesity when groups of individuals are compared.

The mean of the thoracic diameters for the athletes is 1 inch (2.54 cm.) greater than the corresponding measurement for the naval group possessing a similar average value for specific gravity.

RESIDUAL AIR AND VITAL CAPACITY

A value of 1,450 cc.¹ can be used as a group average for residual air volume without appreciably altering the results.

The values for vital capacity in athletes are considerably higher than the corresponding value obtained on naval personnel. Apparently there is no relationship between specific gravity and vital capacity.

COMMENT

The data obtained on seventy-five naval men in the present investigation are in accord with the previous measurements obtained on a similar group of ninety-nine men¹ as shown in the tabular summaries.

Weight in Relation to Specific Gravity.—With reference to the group of athletes it is observed that an average weight of 200 pounds (90.9 Kg.) is associated with a high value for specific gravity of 1.080, and that in even six of the heaviest men of the group, average weight 230 pounds (104.5 Kg.), the average value for specific gravity was 1.059. This fact supports the concept that adipose tissue and not weight per se is the governing factor determining specific gravity.

Among naval personnel¹ an average value for specific gravity of 1.081, and in the group listed in table 3 of 1.086, was associated with weights of 149 and 157

pounds respectively. The chief physical difference between the exceptional athlete and naval personnel possessing similar tissue densities is approximately 50 pounds (22.7 Kg.) of body mass.

Stature.—Associated with the increase of weight is a taller stature of 2 to 3 inches for the athlete compared with the man in the military service. Whether or not this characteristic means that skeletal size in relation to body mass is an important factor that enables the athlete to maintain a high corporeal density despite the increased weight cannot be determined from the anthropometric data.

Specific Gravity in Relation to Height-Weight Tables.—The criterion as to the proper weight of an individual is based on a relationship between stature and absolute body weight, modified by age. Numerous sturdy persons, however, exceed by 15 per cent the weight values recorded as average for a given height. Rejections for military service, for example, on the basis of overweight might serve to eliminate outstanding athletes.

A more valid basis than standard height-weight tables for an estimate whether or not an individual is obese is not absolute weight but rather specific weight; that is, weight in relation to unit volume of tissue.

The plotted data (fig. 1) show the relationship between specific gravity and weight per unit of height.

If an arbitrary value for specific gravity of 1.060 is taken as the dividing line separating qualified men from those not qualified because of excessive fat, two of the twenty-five athletes would be eliminated.

On the basis of the standard height-weight tables used by insurance companies and in the military ser-

Fig 2—A, represents the position assumed by the subject for measurements of anteroposterior and lateral chest diameter. The measurements were taken at the level of the nipple line as described in the text. B represents the position assumed for measurements of the circumference of the chest and abdomen. The latter measurements were taken at the level of the umbilicus.

vice, seventeen of the twenty-five athletes could be considered as not physically qualified for military duty or first class insurance risk, if an allowance of 15 per cent above the average values in the tables is considered as the upper limit.

Of the seventeen rejected "all-American" football players, eleven fall into the group possessing high corporeal specific gravity. According to our classification these eleven men are in prime physical condition if the absence of excessive fat is a criterion of fitness. The type of physical exertion, moreover, that these men are called on to make is proof of their sturdy physique, estimated in terms of speed, agility and endurance.

We propose, therefore, the classification of men as overweight on the basis of specific gravity of the body mass, using a tentative dividing line of 1.060 for the elimination of the obese.

This division, following a line parallel to the abscissas (fig. 1), is diametrically opposed to a division based on height-weight tables, which follow a line at right angles to the abscissas (fig. 1).

THE SURGICAL APPROACH TO HYPERTENSION

GEZA DE TAKATS, M.D.

HOWARD E. HEYER, M.D.

AND

ROBERT W. KEETON, M.D.

CHICAGO

Hypertension is a common symptom of several fundamentally different disorders. Its medical treatment in the past has consisted of rest, the use of sedatives, vasodilators and toxic depressants and psychoanalytic sessions.¹ It can be safely stated that none of these measures have ever cured or arrested the progress of hypertension, although their temporary, palliative value, especially in the early stages, cannot be questioned. Recently a depressor substance has been isolated from the normal kidney and used in lowering the blood pressure of animals and of man.² It is too early to judge the merits of this extract in combating hypertension. The fact remains that cardiovascular-renal disease, with hypertension as its dominant symptom, stands first in the mortality list today and is responsible for more than half a million deaths annually in the United States. After the age of 45 the death rate from this condition is four times that from cancer and twenty times that from either tuberculosis or diabetes³ (fig. 1).

With the recognition of entities such as tumor of the chromaffin system⁴ and unilateral renal disease producing hypertension,⁵ certain surgical indications have been crystallized and have received general acceptance. There remains, however, the overwhelming majority of hypertensive patients about whose classification and treatment there is much disagreement. The

early surgical efforts of Italian surgeons, followed in this country by the pioneer work of Adson, Peet, Heuer and other investigators, have given a great impetus to progress in the surgical therapy of hypertension.⁶ With increasing experience and frequent exchange of ideas, certain fundamental questions regarding selection of cases and operative technic have become standardized in several clinics. It is our purpose here to describe our classification, preoperative study, indications and technic and the early and late results.

A group study of hypertensive patients is essential, uniting ophthalmologist, pathologist, urologist, internist and surgeon for the common purpose of determining the optimal course of management. Such a cooperative effort, in which all participants speak the same language and in which no group tries to dominate the other or rationalize the other's undertakings, saves many a patient from useless operations and results in an unbiased follow-up study of surgical results.

PATIENTS STUDIED

The number of patients treated is small but the study covers the period from 1932 to 1940, with no patient included who was treated after December 1940, so that the minimal period of follow-up study is six months (table 1). It is obvious that with increasing experience, with the use of routine pyelograms and, if necessary, differential tests of renal function the diagnosis of so-called essential hypertension will yield to a more specific one. Thus, all the patients with this diagnosis were thought primarily to have nonrenal, essential hypertension with no or insignificant urinary abnormal-

Fig. 1—Mortality statistics taken from the data of the Metropolitan Life Insurance Company (from Dublin, L. I., and Lotka, A. J.: Twenty-Five Years of Health Progress, New York, Metropolitan Life Insurance Company, 1937)

ities. The history, the renal biopsy specimens taken at operation and the postoperative course led to a recognition of the true nature of the disease. Atrophic pyelonephritis,⁷ lupus kidney,⁷ congenital hypoplastic kidney⁸ and adrenal medullary tumor⁴ are becoming recognized causes of chronic diastolic hypertension. We are impressed with the frequency with which toxemia of pregnancy and pyelonephritis of pregnancy also figure in the history of hypertensive women.⁹ The pituitary origin of some hypertension is still debatable.¹⁰ The emphasis on renal disease in essential hypertension in human beings does not mean, however, that the con-

stitutional, hereditary factors and the neurogenic and endocrine types of hypertension do not play an important part. We have used a modification of Schroeder and Steele's¹¹ classification for a working basis (table 2). This classification well represents our present state of knowledge. In an attempt to assign to these various factors a proper relationship, Edward Weiss¹ has con-

structed a diagram which illustrates them (fig. 2). This diagram simply means that the presence in a person of one factor, such as renal ischemia following eclampsia, with a noncontributory family history and no constitutional factors, may not lead to hypertension, whereas in another person a small emotional, environmental or toxic stress may bring on hypertension because of the inherent vascular reactivity of the patient or because of his glandular makeup.

THE PREOPERATIVE STUDY

The purpose of preoperative study was (1) to establish criteria for the selection of patients for operation and (2) to provide a yardstick with which the benefit derived from the operation could be measured objectively. The data were summarized on one chart and the examinations repeated every two to three months after the operation (table 3). On the basis of these

* Modified from Schroeder and Steele.¹¹

studies it was possible to grade most patients readily into one of the four groups of Wagener and Keith.¹² A similar grouping has been adopted by Palmer and his associates¹³ at the Massachusetts General Hospital

(table 4). Most patients fall into one of these groups; a given patient may have severely progressive hypertension and pass from group 1 to group 4; in other patients the disease may be stationary for many years.

SELECTION OF PATIENTS FOR OPERATION (TABLE 5)

From the study of reports in the literature and our own results, we feel that patients with grade 4 hypertension (malignant nephrosclerosis) are not benefited by any of our operative procedures. True enough, for these patients, who are often young and hopelessly lost, any attempt which carries a low surgical mortality is justifiable. Our records of 8 such patients would indicate that despite subjective improvement lasting for a variable period no objective relief has been gained. Interestingly enough, the renal extract of Page¹⁴ gave subjective and objective relief for similar patients as long as the substance was administered. When the material becomes available there may be something that can be done for such patients. In groups 2 and 3 patients are greatly improved if complete splanchnic nerve section is performed, whereas in group 1 complete cures have been observed. Caution is necessary to prevent confusing the early hypertension of young persons in group 1 with arteriosclerotic hypertension of patients in the fifties. The latter have a high pulse pressure and may have a high systolic pressure, but their diastolic pressure is frequently around 100

Fig. 2.—Pathogenesis of hypertension (redrawn from Weiss¹). The base of the pyramid is made up of constitutional and hereditary factors.

mm. of mercury. This frequently occurring type of hypertension, due to an atheromatous aorta, is not within the scope of our discussion.

SURGICAL PROCEDURES

Besides the stage of the disease in which the operation is undertaken, the technical procedure is an important factor in the results obtained. In our clinic the following procedures have been used:

1. *Supradiaphragmatic Splanchnic Nerve Section.*—In this operation one interrupts the splanchnic nerves above the diaphragm and excises the ninth to the twelfth sympathetic ganglions. The operation was originally described by Pieri¹⁴ and was performed in 1932 by one of us¹⁵ to increase the insulin sensitivity of a patient with juvenile diabetes and was popularized by Peet.¹⁶ The operation does not permit the examination of the kidney and the adrenal gland and cannot interrupt the lumbar sympathetic nerves, whose part in the mechanism of postoperative relief will be discussed.

2. *Infradiaphragmatic Splanchnic Nerve Section.*—The splanchnic nerves are severed below the diaphragm, together with a small slice of the celiac plexus. In addition, the first and second lumbar ganglions are removed. The procedure described by Pereira¹⁷ has been modified by Craig.¹⁸ We have used Flothow's¹⁹ muscle-splitting anterolateral approach to the lumbar sympathetic nerve.

enopathy, the identification of all the splanchnic trunks may be difficult. Finally, branches that are given off toward the periaortic plexus from the splanchnic nerves and the sympathetic chain above the diaphragm are missed by this operation.

3. *Transdiaphragmatic Splanchnic Nerve Section.*—This operation combines the advantages and eliminates

Grade 4 hypertension
Cardiac decompensation
Nitrogenous retention
Severe atheromatosis of larger vessels
Age over 50

convexity of the kidney and an omental flap or a pedicled muscle flap is sutured into the incision. The operation was first done in our clinic in 1936, and 5 cases were reported last year.²¹ Nine cases were reported by Bruger and Carter.²²

5. *Nephrectomy.*—This is done for unilateral renal disease associated with hypertension when there is no detectable impairment of function in the opposite kidney. One patient was available for study in the group.

6. *Renal Biopsy.*—A small slice (1.5 cm. long and 3 mm. thick) of renal cortex was removed during the transdiaphragmatic and infradiaphragmatic sympathectomies and during the renal grafts. A total of fifteen biopsies were performed, and their value will be discussed hereafter.

RESULTS

Thirty ^{22a} patients have adequate follow-up records, by which it is meant that they were reexamined by one or several of us at intervals of two to three months. There

TABLE 6.—The Surgical Approach to Hypertension as Influenced by Technic and by the Stage of Disease

were 4 patients with supradiaphragmatic, 15 with infradiaphragmatic and 5 with transdiaphragmatic splanchnic nerve section. Five had an omental or muscular graft

and 1 nephrectomy for hypertension. There was no surgical mortality. We believe that at least two readily recognizable factors influence results (table 6). One is the type of operation performed and the other the stage of the disease in which the operation is undertaken. Of the splanchnic nerve sections the supradiaphragmatic and the infradiaphragmatic operation yielded such doubtful results that they were discontinued. The transdiaphragmatic, total splanchnic nerve section has given us excellent results in patients with grade 1 and grade 2 hypertension and produced considerable subjective relief in 1 patient with grade 3 hypertension. In 1 patient with malignant nephrosclerosis it failed. Of the 5 patients with grade 4 hypertension in whom a renal graft has been undertaken, only 1, who has now been followed for five years, has had subjective relief. One patient who had nephrectomy for unilateral atrophic

Fig. 3.—Postural hypotension three months after extensive splanchnic nerve section and lumbar sympathectomy. The pulse volume was small in the standing position; the blood pressure had dropped from 120 systolic and 75 diastolic to 95 systolic and 70 diastolic. For six weeks after the operation the blood pressure could not be obtained after the patient had stood five minutes.

pyelonephritis and 1 who had nephrectomy for congenital hypoplastic kidney had complete subjective and objective relief up to the time of this writing.

COMMENT

If one looks on diastolic hypertension as a malignant process progressing with a varied speed but with unpredictable periods of acceleration, an analogy with the surgical treatment of carcinoma readily presents itself. Just as in the case of cancer, methods may well be developed which would make surgical intervention unnecessary; the joint efforts of Tinsley Harrison and Irvine Page may do the same for the surgical treatment of hypertension.⁶ It is our feeling at present, however, that if the not too advanced ischemia of the kidney can be remedied by sympathectomy or vascular grafts the formation of the yet poorly understood pressor substances will be inhibited, so that substitution therapy with renal extracts will not be needed. That a gradual improvement of renal circulation occurs after splanchnic nerve section can be demonstrated by the slow fall in blood pressure and the improvement of urea clearance over a period of six to ten weeks which one observes in

22a. Since this paper was written an additional 10 patients have had a transdiaphragmatic splanchnic nerve section. With the exception of 2 patients in whom the operation was incomplete, the response to this procedure was equally satisfactory.

28 Oliver, J.: The Architecture of the Kidney in Chronic Bright's Disease, New York, Paul B. Hoeber, Inc., 1939.

postmortem records of Blackman²⁹ should be cited. He frequently observed atheromatous plaques at the origin of the renal artery in the kidneys of patients with essential hypertension. Such kidneys have a relatively intact terminal vascular bed and could be vascularized with more ease than a kidney with arteriolar sclerosis.

The exact indications for the vascular graft are not yet clear. It is our feeling that in cases of late atrophic pyelonephritis or of grade 3 essential hypertension, when splanchnic nerve section alone cannot bring about adequate revascularization of the kidney, this operation might be added to insure a maximal blood supply. The combined operation has kept a child of 8 with congenital hypoplasia of both kidneys and grade 4 hypertension alive and symptom free for more than two years and has kept another patient with grade 4 hypertension alive for more than six years in an essentially unchanged condition (fig. 6).

As indicated in the tabulation of results, we believe that the selection of the patient and the selection of the surgical technic are the two important factors in bringing about results. When all types of patients were operated on by an approach which did not permit complete splanchnic nerve section (Rytand and Holman³⁰), there was a 20 per cent surgical mortality and 27 per cent more of the patients died a year and a half after operation. Rytand and Holman's courageous attempt serves to reemphasize the limitations of surgical therapy. The work of Keith and Smithwick in establishing the grades of hypertension and the best technical procedure has been coordinated in this study to bring about optimal results. At present, at least, the total sympathectomy practiced by Grimson, Alving and Adams²³ seems unnecessarily radical but may become the operation of choice if the present operation will not maintain its efficiency in the five year follow-up records.

SUMMARY

1. Thirty patients with essential hypertension (benign and malignant nephrosclerosis) were subjected to operative procedures.

2. The hypertensive state was classified as early, moderate, marked and malignant, after the classification of Keith and his associates. It was noted that malignant hypertension is a contraindication to operation.

3. The surgical procedures used were the supradiaphragmatic, the infradiaphragmatic and the transdiaphragmatic splanchnic nerve section, the vascular implant to the kidney and nephrectomy. Of the splanchnic nerve sections, the transdiaphragmatic section of Smithwick produced the only real reductions of high blood pressure. The value and the place of the vascular implant to the kidney are still unclear. Nephrectomy in 1 case was successful.

4. No method has come to our attention so far which would check the progress of hypertension more effectively than surgical therapy. The selection of patients with early hypertension and the use of an improved technic seem to be two important factors in obtaining good results.

5. Outside the actual lowering of blood pressure, the gradual improvement of renal function, the postural hypotension and the decrease in reflex nervous irritability due to adrenal denervation constitute the mechanisms of the relief obtained.

122 South Michigan Avenue—8 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. REGINALD H. SMITHWICK, Boston: Dr. de Takats and his collaborators have raised the question Does complete denervation of the splanchnic bed of hypertensive patients offer more in the way of persistent and significant lowering of blood pressure than does partial denervation of the splanchnic bed? The splanchnic bed is completely denervated when shortly after operation the blood pressure in the standing position completely disappears or falls to a level that is incompatible with this upright position. The splanchnic bed is partially denervated when after operation there is no significant difference between the blood pressure in the standing position as contrasted with the horizontal position. Sixty-six unselected patients had partial denervation of the splanchnic bed. There was a fairly equal representation in each stage of the disease. Significant and persistent lowering of blood pressure was obtained in 9.1 per cent of these patients. A series of 38 patients had had complete or near complete splanchnic denervation, as judged by significant fall in blood pressure in the upright position after operation. Seventy-one per cent of these have had significant and persistent lowering of the blood pressure during the period of observation. The majority of the good results or the highest percentage were in groups 1 and 2, 87 per cent. However, a very significant effect (60 per cent) has been noticed in group 3 and particularly in group 4 cases. The results in the latter group do not allow me to agree with Dr. de Takats' statement regarding malignant hypertension. I do not believe that malignant hypertension is necessarily a contraindication to surgery. My impression from this rather preliminary surgery of a very small group of patients followed for six months to two and a half years after operation is that radical denervation of the splanchnic bed has more to offer patients with hypertension than partial denervation of the splanchnic bed.

DR. CLAUDE BECK, Cleveland: Dr. de Takats deserves admiration for his well directed efforts to explore further the function of the autonomic nervous system in human hypertension. To the question as to whether or not our present surgical procedures for essential hypertension are curative the answer must be "No." However, to the question as to whether or not in properly selected cases they effect results which are sufficiently palliative to be justifiable the answer is definitely "Yes." They are not curative because they do not remove the cause. The primary seat of the disease process in cases of essential hypertension is in the blood vessel walls themselves, particularly the blood vessels of the kidney. Nowhere more than in Cleveland can it be stressed that substances derived from the kidney can modify blood pressure and the circulation. Evidence seems to indicate that there are persons who are prone to develop hypertension because of the intrinsic properties of their blood vessels. Persons most likely to develop hypertension are born with a vascular tree hyperdynamic in its response to physical, nervous and humoral influences. Denervation of the renal vessels could be expected only to check or ameliorate a process which is primary in the vessels walls themselves and capable of progression without nervous influences. That the nervous system may play a significant role in the initiation and development of human hypertension is admitted by all. In man the nervous system is probably mostly concerned in the initiation of the hypertensive state. Consequently the plea is made again that persons giving adequate evidence that they probably will develop a fixed hypertensive state should be urged to have their kidneys and adrenals denervated. The surgeon's degree of success with such cases will vary directly with the timeliness of surgical intervention. The operation for essential hypertension as generally performed results in denervation of the adrenals as well as of

29. Blackman, S. S., Jr.: Arteriosclerosis and Partial Obstruction of the Main Renal Arteries in Association with "Essential" Hypertension in Man, *Bull. Johns Hopkins Hosp.* 65: 353, 1939.
30. Rytand, D. A., and Holman, E.: Arterial Hypertension and Section of the Splanchnic Nerves, *Arch. Int. Med.* 67: 1 (Jan.) 1941.

the kidneys. This must result in a diminution of the amount of epinephrine released especially during stress. Experimental evidence is at hand to show that the smooth muscles of hypertensive animals respond hyperdynamically to epinephrine, and it is possible to show that epinephrine can stimulate the central nervous system directly. The symptoms from which relief is secured are "nervous" in origin. On a perfectly reasonable basis denervation of the adrenals thus could be expected to lessen the nervous response to both centrally and peripherally directed nerve impulses. This is offered as an explanation for clinical improvement from nervous symptoms in patients in whom no blood pressure drop is secured. I would voice some skepticism about the necessity of extending the scope of our surgical procedures more and more, especially when early cases are available for treatment.

DR. GEZA DE TAKATS, Chicago: There are two points I should like to bring up in closing the discussion. One is the definition of malignant hypertension. Obviously, this is the crux of the situation. If one follows the classification of Keith and Wagener closely one will note that group 4 hypertension shows papilledema, retinal hemorrhages, loss of renal function and cardiac impairment. Now, obviously, the patients in Dr. Peet's series and perhaps in Dr. Smithwick's series that were getting results in spite of a group 4 hypertension may have been in an early malignant phase. That is, they had a papilledema although the renal function was intact. In this sense I agree that this group should be operated on. However, the completely developed group 4 hypertension, with a urea clearance of 20 cc. per minute or less, in our experience has always failed to respond to surgery. About Dr. Heinbecker's discussion regarding the importance of primary vascular involvement in the kidney, we are sure that this holds for a number of cases. We are becoming more and more conscious of infectious diseases producing early arteriolar changes. In our series we have patients with hypertension, so-called essential hypertension, with well proved rheumatic infection in childhood. I am sure that rheumatic arthritis and vascular changes after toxemia of pregnancy can cause hypertension. Nevertheless the clinical results are so impressive that, regardless of where the infection came from or what the origin of the renal changes is, splanchnic nerve section should be done. In a report by Dr. Kahn there is a suggestion that if the less complete, partial sympathectomies fail, then perhaps an extension of the operation should be done such as Dr. Smithwick has suggested. That is just exactly the stage that we have gone through. Time and limitation of space did not allow me to discuss the fact, but we have had 15 patients who have five or six year follow-ups in whom high blood pressure has recurred almost to the preoperative level. Three of them were reoperated on by the Smithwick method and are now classed as cured.

Ibsen Was a Pharmacist.—The great Nordic dramatist Henrik Ibsen was a pharmacist for six years. At the age of 16 he became an apothecary's apprentice in the pharmacy of Griemstad, in three years passed the "assistant" examination and for three more years manufactured medicines and ointments in the pharmacy. Did this pharmaceutical occupation enter into Ibsen's dramatic creation? By no means, although we meet much of medical interest in his plays, and especially a rich psychopathologic casuistry, to which belong types such as Oswald Alving in *Ghosts*. Only in one place, where one would least expect it, in the metaphysical drama *Brand*, the two words quantum satis (q. s. in prescriptions) testify to Ibsen's association with pharmacy. They are found in the stirring four concluding lines of the play. Brand, the Nordic Faust, at the end of his life cries that he has sacrificed himself to the principle "all or nothing":

"God. I plunge into death's night.
Does not lead us to thy Light
Manly effort's quantum satis?"

SHORT WAVE THERAPY IN THE TREATMENT OF SINUSITIS AND ALLERGIC RHINITIS

A STATISTICAL EVALUATION

GEORGE R. BRIGHTON, M.D.

VILLIAM BENHAM SNOW, M.D.

AND

HERBERT S. FRIEDMAN, M.D.

NEW YORK

The advent of short wave therapy on the therapeutic horizon in the past ten years has brought forth exorbitant claims regarding its efficacy. These have encouraged its indiscriminate use by the medical profession, often on the insistence of the patient. Our purpose in this report is to demonstrate the limitations of and indications for this increasingly popular form of physical therapy in intranasal disease by statistical analysis of 160 cases¹ of acute and chronic sinusitis and of allergic rhinitis treated by short wave therapy in Vanderbilt Clinic in the past three years.

Gale² in 1935 reported "it is yet too early to go into the causes for the results obtained, but, from the experience gleaned from treating fifty chronic sinus conditions, I believe the ultra short wave to be the best means of combating sinus conditions at present." Tebbutt³ in the same year and Talia⁴ two years later reported equally good results from the use of short wave therapy but extended its scope to the acute infection as well. Tamari⁵ in 1932 advocated the application of this modality of physical therapy to allergic rhinitis.

More recent publications, however, have questioned the universal benefit of short wave therapy. Hollender⁶ in 1939 wrote that "short wave diathermy is an effective therapeutic aid to other procedures but is practically valueless in the large majority of cases of chronic diseases of the maxillary sinus." His conclusions favor its use in acute sinus infections. The report of the Council on Physical Therapy⁷ stated in 1939 that infrared and short wave diathermy "are useful adjuncts to other treatment after adequate drainage has been established. Medical diathermy is of value in the relief of pain: the frontal and maxillary sinuses are most suitable for treatment."

Our statistical survey would indicate that, at best, short wave therapy, if combined with other routine measures in common use by the otolaryngologist, is to be recommended only for the alleviation of pain and diminution of discharge in chronic and subacute sinusitis. It has no therapeutic value in allergic rhinitis and it does not appear to expedite the recovery of acute sinus infections, in which the prognosis with adequate conservative therapy has been found to be favorable.

The cases considered in this series, with the exception of the allergic group, were for the most part observed

and treated during the unseasonable winter and spring months. It is not within the scope of this survey to consider climatic factors, bacterial flora and other less obvious variables. Rather, it has been our aim to analyze the therapeutic results in a moderate sized group, showing a cross section of the incidence of sinusitis in this locality.

THEORETICAL CONSIDERATIONS

The effect of short wave diathermy on man was noted by Gale³ in 1927 when he reported the rise in temperature in workmen exposed to high frequency electric currents in the vicinity of radio transmitters. The striking property of oscillations below 30 meters to pass through mediums of poor electrical conductivity was well illustrated by this worker. An 8 meter wave was passed through a series of glass receptacles containing, in order, 0.1 per cent potassium permanganate, tap water and a 3 per cent salt solution. At the end of ten minutes the salt solution had risen in temperature from the room level of 78 F. to 93 F., while the other fluids changed less than 3 degrees F. The concentration of short wave heating effect in good conductors as compared with those in poorer conductors is the rationale for heating the nasal and sinus mucous membrane. The ability of short wave emanations to penetrate bone is likewise of basic importance.

In conventional long wave diathermy machines the frequency employed is usually in the region of 1 million cycles a second (wavelength 300 meters) while in the short wave machines 10 to 50 million oscillations per second are produced (30 to 6 meter wavelengths). Short wave currents have the great advantage over diathermy emanations in that they permit transmission from machine to patient without metallic contact. This greatly reduces the danger of burns and adds to the ease of application of short wave machines. In calculating the dosage in short wave therapy the "lamp load" output of a machine is only of relative importance because of the great number of variables in technics of application: the patient's tolerance is the most important guide.

TABLE 1.—Allergic Rhinitis

Number of Cases	Patients Showing Significant Improvement on Short Wave Therapy	Patients Showing Improvement After 3 Month Follow Up	Patients Showing No Change During or After Therapy
25	16%	0%	84%

The opinion of most American observers concerning tissue heating is that differences in power output of the machine and the technic employed play a more vital role than the actual length of the short wave, per se. The preference expressed by many continental observers for the shorter wavelengths (6 to 12 meters) in intranasal therapy seems to be based on acceptable clinical evidence. The use of the 1 and 2 meter machines now being employed by a few workers has not been adequately reported.

There has been a tendency to ascribe to short wave action on human tissue many mysterious therapeutic properties other than the production of heat. Specific bactericidal effects,⁸ antibody formation,⁹ histamine-like

response¹⁰ and athermic action¹¹ have all been defended. But, as pointed out by Hollender, who quotes the Council on Physical Therapy,⁶ "In the light of present observations the consensus seems to be that no physiologic effects other than those attributable to heat have been substantiated."

In the light of our present knowledge, the action of heat in the nasal mucous membranes may be said to be one of hyperemia and hyperlymphia. By dilating the vascular bed and stimulating the flow of lymph, heat artificially aids in much the same way as any natural inflammatory process in controlling local infectious

TABLE 2.—Acute Purulent Sinusitis

Number of Cases	Per Cent Showing Decided Improvement	Per Cent Showing Moderate Improvement	Per Cent Showing No Improvement or Worse
25	32	44	24

processes. Should adequate nasal and sinus drainage exist, the beneficial results of heat produce their maximum effect.

However, in a nondraining empyema of a closed sinus space the increased turgescence and secretion of the nasal mucous membrane simply adds to the pain and tenderness already present. As mentioned by Titus,¹² "it is important first to shrink down the nasal mucous membrane so that the natural openings of the sinuses may be available to give relief from the pressure which will obviously be increased by the treatment." We are furthermore of the opinion that, in those acute cases in which simple shrinkage does not afford adequate sinus drainage, sinus irrigations by natural ostium or trocar, and not short wave therapy, are the procedure of choice after a trial period of ten days to two weeks has elapsed.

TECHNICAL CONSIDERATIONS

Selectivity of tissue heating in the short wave field occurs in inverse relation to the frequency of the oscillations. Presumably the shorter the wavelength of the apparatus used (more frequent oscillations) the more uniform will be the heat generated in the tissue.

To date the accepted version of the effects of short wave in therapy is that any favorable result is brought about by the heat produced in the tissue treated and by the accompanying physiologic response to such heat.

Many claims have been made for short wave in treatment of sinus disease, and in checking these it appears to us that wavelengths throughout the entire range of commercially available equipment have been utilized and reported on with varying degrees of enthusiasm.

Physically one would expect the most uniform heating of bone underlying soft tissues using commercial equipment at 6 meters. The additional advantages of all 6 meter equipment is the fact that it permits the use of space or noncontact electrodes with arms. This method of application over the face is uniformly simple and convenient.

We wished to secure some of the advantages of this method of application and also wished to ascertain deliberately the effect of short wave out of the 6 meter range. We selected an apparatus, A. M. A. Council accepted, of 12 meters with sufficient output to permit the use of arms with spacing. We feel that any favor-

12. Titus, N. E., in discussion on Jourard.

able result at this wavelength would be more representative of similar effects to be expected both above and below this point in the short wave scale.

The machine, a standard model, employs four tubes and operates on 60 cycles, 103-130 volts. The lamp load output is 400 watts with a maximum input of 1,200 watts.

Application.—In all cases a disk 7 inches in diameter was placed over and parallel to the nose and forehead of the patient, the electrode centered over the bridge of the nose. The other electrode was placed anteriorly over the sternal region, the edges of the disks approximately 11 inches apart.

The facial electrode was pressed firmly in contact with the nose and forehead, only six thicknesses of thin linen towel separating the electrode from the skin. (If this electrode is not in firm contact, uneven heating occurs and much prickling and potential burning.)

The sternal electrode was placed at a distance of 3¼ inches from the anterior chest wall with air spacing only.

By this technic the maximum heat is felt over the anterior face. Less heat is always produced beneath the other electrode. The current was turned to the maximum tolerance of each patient.

The duration of the application was fifteen minutes.

Frequency.—Treatments in acute cases were given daily and preceded immediately by the usual nasal procedures to assure free drainage. In the chronic cases the treatments were given three times a week. The maximum number of treatments in all cases was limited to six weeks, with a total of eighteen treatments in chronic cases.

SHORT WAVE THERAPY IN THE TREATMENT OF ALLERGIC RHINITIS

Twenty-five typical cases of allergic rhinitis as proved by history, cutaneous tests and clinical findings were treated by short wave therapy. In 6 of this number, in which there was a history of seasonal attacks of coryza, therapy was given three weeks before the allergic

period as well as three weeks after the appearance of the acute symptoms. All 25 patients received the usual dosage of short wave therapy three times a week for a total of six weeks.

Our results are summarized in table 1. It is apparent that none of our allergic patients showed any permanent benefit from short wave therapy and that only 16 per cent revealed significant temporary relief from any or all of their complaints, which included nasal discharge and obstruction, sneezing and conjunctival irritation.

ACUTE SINUSITIS

Another group of 25 patients suffering acute purulent infections of the paranasal sinuses were treated by short wave therapy. Patients in this group gave histories of

symptoms of less than three weeks' duration and of no previous sinus infections. The great majority of our cases were of maxillary or frontal empyema but accompanying ethmoid and sphenoid disease was present in a few. Diagnosis was determined by the usual clinical and x-ray methods.

In these acute cases, short wave therapy was applied three or five times a week for two weeks. In 18 of the cases daily clinic therapy consisted of nasal shrinkage and irrigation as well as home administration of benzoin or menthol inhalations. In the other 7 cases in this series only ephedrine drops for home application were prescribed.

TABLE 4.—Chronic Sinusitis

Purulent.....	38	24	12	64%	8
Nonpurulent.....	72	62	15	25%	19

* Total, 110 cases.

Table 2 summarizes the results obtained in the acute sinusitis group. In 32 per cent of the cases studied there was significant and rapid resolution of symptoms within five days and a somewhat more gradual appearance of objective improvement. Forty-four per cent of the patients were moderately relieved of their acute symptoms after two weeks, leaving in all 24 per cent, or about one fourth, who showed no improvement or became worse on the regimen described.

These persistent cases, which must be classed as failures, responded well to antral irrigations by trocar or natural osteal, frontal and sphenoid washings and, in 1 case of frontal sinusitis, to removal of the anterior tip of the middle turbinate. A 5 per cent solution of zinc peroxide instilled through trocar or cannula was found to be of special value in antrums yielding a foul, broken down, purulent discharge.

Of the special group of 7 patients treated only by short wave therapy and ephedrine drops applied by the patient, 4 were destined to fall into the failure class. These patients occasionally complained of increased headaches and transitory dizziness following physical therapy.

Table 3 analyzes these 25 cases of acute sinusitis by considering the effect of short wave therapy on the more common symptoms and signs, individually, when present. These include headache or localized pain, nasal discharge, obstruction to breathing, sinus tenderness and postnasal drip.

Of interest in this analysis is the fact that no single sign or symptom was greatly relieved by short wave therapy in over 38 per cent of the cases. The most universal improvement was seen in relief of headache, while in those 14 patients suffering from sinus tenderness only 16 per cent were significantly relieved and 50 per cent became worse or showed no improvement on physical therapy. We are of the opinion that the finding of maxillary, ethmoid or frontal tenderness indicates sinus involvement of a severe degree and usually with poor drainage. These factors may account for the very poor results of short wave therapy in patients showing this sign, and our results would contraindicate physical therapy until drainage has been established.

CHRONIC SINUSITIS

One hundred and ten patients suffering from chronic sinus disease were treated by short wave diathermy three times a week for six weeks. In this series 38 patients were shown by x-ray examination and sinus irrigations to have a purulent involvement of one or more paranasal cavity. During six weeks of physical therapy, as shown in table 4, 24 per cent of the group designated as chronic purulent sinusitis reported symptomatic relief. However, when again reviewed three months later, only 8 per cent of this series had maintained any prolonged benefit from their short wave therapy. Although observed regularly in the ear, nose and throat clinic during their period of physical therapy, these patients received only symptomatic rhinologic therapy such as tampons of mild protein silver and nasal irrigations. Sinus irrigations were performed only for diagnosis and relief of pain. In several cases a decrease in the amount of intranasal secretion and mucosal edema was noted, but no cases were seen in which sinuses previously black on transillumination or x-ray examination became appreciably clearer. In both

TABLE 5.—Symptoms of Chronic Sinusitis

	Number of Cases showing Symptom	During Short Wave Therapy			At 1 Month Follow Up, per Cent Showing Improvement
		Per Cent Decidedly Improved	Per Cent Moderately Improved	No Change	
Headache (pain)	78	72	20	8%	48
Discharge	90	48	27	25%	18
Obstruction	62	38	28	34%	23

Isolated upper respiratory infection	10	50	10	40%	40

* Total, 110 cases

this and the chronic nonsuppurative group to be considered next, most improvement claimed was symptomatic rather than objective.

Seventy-two patients with chronic nonpurulent sinusitis were observed during a six week course of short wave therapy. In this group the typical findings were hyperplastic nasal membranes with perhaps a mucoid discharge on occasion but no purulent discharge. (Nine of these patients, to be discussed separately, had previous multiple intranasal operations.) These patients complained of one or all of that familiar quartet mucoid nasal discharge, postnasal drip, headache and nasal obstruction. As presented in table 4, 62 per cent of the patients felt much improved during physical therapy, but of this number only 19 per cent were clinically or symptomatically benefited after a three month follow-up.

The more frequent signs and symptoms of the entire 110 cases of chronic sinusitis are considered individually in table 5. Again we find the highest percentage of success to be in the relief of headache. In this symptoms group 72 per cent of the patients reported improvement during short wave therapy and 48 per cent showed continued relief three months later. Thirty patients complaining of sinus tenderness were entirely unaided by short wave on three month follow-up and only 6 per cent benefited during their six week course of therapy. Relief from recurrent upper respiratory infection was reported by 5 patients of 10 who volunteered this as their outstanding complaint.

Nine patients classed in the chronic nonpurulent sinusitis group who had previously undergone multiple sinusal operations but who presented themselves with continued nasal complaints were studied during a six week course of physical therapy. Two of these patients were greatly benefited by short wave treatment, while 4 more reported partial relief from their complaints.

COMMENT

The negligible effect of short wave therapy on allergic rhinitis is not unexpected. In our clinical studies the usual immediate post-therapeutic effect of short wave application has been one of increased turgescence of the nasal mucous membranes. We have failed to note any secondary dehydration of more than a temporary nature which might successfully influence the mucosal edema of allergic rhinitis.

Our statistics in the acute purulent sinusitis group reveal that 24 per cent, or about one fourth of our cases, did not respond to short wave therapy combined with simple nasal shrinkage. While these figures compare unfavorably with those of Furstenberg,¹³ who reports 95 per cent cures on simple nasal therapy in a carefully controlled group of college students living in a more sheltered environment, they closely approach the average of clinic groups in this section of the country. It would therefore appear that the added expense and time required by short wave therapy does not appear to be indicated in the acute sinusitis sufferer until other simple otolaryngologic methods have failed. Those cases presenting sinus tenderness particularly contraindicate short wave therapy, as they usually signify inadequately draining sinuses and are rendered worse through increase of the edema and secretion of mucous membrane lining these cavities.

For the patient with chronic suppurative sinusitis we believe that sinus irrigations and intranasal operative measures facilitating drainage are the procedures of choice, as only 8 per cent of our patients showed persistent (three month) improvement in their symptom complex on short wave therapy.

In the nonsuppurative group, however, we have found that short wave therapy is of distinct benefit. It is this group that is particularly resistant to any form of therapy, and it is here we find that a total of 77 per cent (62 and 15 per cent) of our patients were aided during their course of physical therapy.

Of note in this group are those unfortunates who after multiple intranasal operations still persist in their symptoms. In a small but significant group of 9 patients of this refractory type, 6 showed much or moderate benefit from the application of short wave treatment.

SUMMARY

1. Short wave therapy is employed indiscriminately in many intranasal conditions in which it does little good and may do harm.
2. It is of no value in allergic rhinitis.
3. Its application in acute sinusitis even in conjunction with nasal shrinkage and irrigations does not produce results superior to conservative nasal therapy alone.
4. In cases of chronic nonpurulent sinusitis which present, in general, a poor prognosis it is of definite benefit, particularly in the relief of headaches.

OBSERVATIONS ON THE TOPICAL USE
OF SULFONAMIDE DERIVATIVES

EDGAR M. BICK, M.D.

Major, M. C., U. S. Army
FORT MONMOUTH, N. J.

The ability of the sulfonamide derivatives to prevent infections in wounds when applied locally has now become well established. The fact has been repeatedly demonstrated in experimental, operative and traumatic lesions and has been fully reported.¹ It is possible by means of such topical application to create not only a high concentration of the drug in the tissue fluids surrounding the lesion but to maintain a degree of hemoconcentration varying from 3 to 4 mg. per hundred cubic centimeters in twenty-four hours to a residual trace a week later following the use of 10 to 15 Gm. in large wounds. While a hemoconcentration at this level is hardly sufficient to combat an established septicemia of any real intensity, it is apparently high enough to prevent its development from a properly treated contaminated wound. The subject is now sufficiently

advanced that generalizations on end results in terms of gross infection are no longer sufficient, and more detailed consideration of different aspects of the problem are required.

In Key and Burford's² 1940 report the suggestion was made that the topical application of sulfanilamide might

delay the healing time of wounds of the soft tissues. They thought that it did, but to an inconsiderable degree. In their later report³ of 1941 it was stated that the use of smaller quantities of the crystals (in the order of 5 Gm.) had proved equally effective and did not cause any apparent delay in healing. Retarded wound healing had been noticed by others in reports on the general problem and has been as frequently denied. In view of this discrepancy I have studied a varied series of cases solely from the point of view of wound healing.

Fifty cases of traumatic and operative wounds of the soft tissues were chosen to be treated by a standard technic consisting of thorough washing with green soap and water and, where indicated, débridement, and saline irrigation followed by simple unmedicated dressings. Primary suture was employed to the extent which the

wound permitted, that is, was total in all but a few complex traumatic wounds and plastic procedures in which certain crushed areas did not permit perfect apposition of skin edges. The more extensive lesions were immobilized by splints, plaster of paris or traction. Powdered sulfanilamide or sulfathiazole was applied in quantities varying from 1.5 to 10 Gm., sufficient to cover all surfaces of the wound. Massive packs of the powder which might form an obvious block to surface approximation were avoided. (The question of the relative bacteriostatic action of these drugs will not be considered here; only their effect on wound healing.) As a control fifty operative and traumatic wounds were observed in which treatment was identical except that no sulfonamide derivative or other medication was used.

In the control group there were four superficial wound infections; in the sulfonamide group there was one infection occurring in a case in which Kirschner wire was used as internal fixation. None of these infections were serious, and all cleared up easily when the wounds were exposed.

Observations were made at frequent intervals, in some cases daily, until effective healing had taken place. By effective healing of a wound is meant the surface to surface apposition of skin and subcutaneous tissues characteristic of primary union of sufficient cohesive strength that on removal of the sutures the apposition remained. During the process of healing a decided difference was observed in the tissue reaction of most of the patients treated with sulfonamide derivatives as against the control group. In the former occurred some features which, had they appeared in nontreated wounds would have indicated, or at least suggested, deep infection. The wound edges were apt to be reddened, often

somewhat swollen and, where granulation tissue was exposed, showed a grayish cast. On several occasions infection was suspected and the wounds probed respectively four, five and eight days after primary suture or operation. Finely granular clumps of sulfonamide derivatives were found still unabsorbed and small quantities extended through the openings. Serosanguineous fluid was commonly found on the dressings and could be expressed from the lesion up to the point

of complete healing. Mixed with the granules the resemblance to ordinary pus was striking. Key's recent observation that the extent of wound reaction decreases with the amount of drug used was confirmed. It may be possible that future observations will disclose a minimum effective dose that will eliminate this reaction,

at least to a large extent. It is important that, meanwhile, the surgeon using topical sulfonamide derivatives be acquainted with this and bear in mind that it is merely a phase in normal healing under the circumstances. If this picture is appreciated, unnecessary probings, early suture removals and secondary wound exposures will be avoided. The appearance is best described as that of a noninfected foreign body reaction in the subcutaneous tissues.

Fig. 4.—Healing twelve days after medial meniscectomy.

In the present series of cases there was no question that wound healing was delayed when powders were implanted locally. This applied even to the cases in which the tissue reaction described was slight. The delay was considerable, representing on the average between 50 and 75 per cent of the time factor. Dressings done on simple lacerations or cleancut incisions were still oozing serosanguineous fluid on the fifth or seventh days in almost all of the cases treated with sulfonamide derivatives and were generally dry in the control cases. In the former, healing was not complete for ten to twelve days and often only in part of the wound surface at that time. In the chart the difference in healing time between the two groups is expressed by a graph. The points represent as nearly as could be determined clinically the time at which wound healing was considered effective. It is conceded that in so expressing these data a large margin of error must be allowed, but it is also submitted that the same margin applies to the two groups. This delay in healing not only causes longer hospitalization or attendance at the clinic but, of greater importance in extremity surgery, delayed the time in which active motion or local massage might have been instituted.

The hair line scar characteristic of primary union in an area of minimal skin stress which occurred normally among the control group was almost never observed among the patients treated with sulfonamide derivatives. With few exceptions in comparable areas the scar of the treated group remained broader at equivalent time intervals than did those of the controls. Since each scar is a unique phenomenon whose multiple factors cannot be duplicated even experimentally, there is no way of submitting comparable measurements. However, among the various types of cases the Jones or anteromedial crescentic incision for excision of a medial meniscus of the knee joint was chosen for

comparison. These incisions are as closely comparable in location, size and depth as are obtainable in surgery of the extremities. Twelve of these were in the cases in which sulfonamide derivatives were used and 14 were in the control group. At any stage of their healing one could distinguish a case belonging to one or the other group with few errors simply by observing the healing scar. In general this observation applied to all comparable cases. The healing of a wound or incision treated with a sulfonamide derivative is very apt to leave a scar of greater breadth and depth than would be formed in a similar instance of primary union when the drug was not used.

It was first thought that the use of a sulfonamide derivative locally left a larger mass of subcutaneous fibrosis than did the untreated cases. This is true in the early weeks of healing. In 2 cases in which secondary operations were necessary the subcutaneous masses were found to resemble grossly the dense grayish tissue characteristic of healing in slowly subsiding infections. Since this was found only in connective tissue areas and since in no case did the deeply palpable masses appear to involve muscle or synovial tissue, it was felt that the sulfonamide derivatives might have the effect of selective stimulation of connective tissue cells. This is here recorded as a temporary phenomenon. With passage of time it was found that the subcutaneous masses characteristically larger in the treated cases than in the control group were absorbed so that in the space of two to four months the tissues beneath the cutaneous scars were equally free.

Few differences could be found in the rate or the type of effective healing between those cases in which sulfathiazole was used and those in which sulfanilamide was used. At this writing it appears that sulfathiazole is somewhat less irritating than sulfanilamide. Further observations will be needed to confirm this. The rate of healing was not significantly different, but apparently because of the less irritant quality a finer scar remained in most instances. Since the most common postoperative contaminant in extremity surgery is the staphylococcus, sulfathiazole is theoretically the more desirable; but since the anaerobes and streptococci are the most common contaminants of traumatic wounds,

Fig. 5.—Healing twelve days after external meniscectomy

sulfanilamide is the obvious choice in such cases. The newer drug sulfadiazine, now commercially available, will be tried in the near future.

In 27 cases the sulfonamide derivatives were applied to wounds in which joint or tendons were exposed. In these instances the drugs remained in contact with synovial and tendon sheath surfaces. At this time no particular unfavorable joint or tendon sheath reactions have been observed in any of the cases and there has been no residual dysfunction peculiar to these applications. This series will be continued and reported later.

CONCLUSIONS

The local applications of sulfonamide drugs to wounds of the soft tissues or cleancut operative incisions in which primary suture is indicated retards healing by at least 50 per cent of the time factor and promotes excessive cutaneous scarring. In extremity surgery this delay in healing time may postpone necessary active motion and massage; in plastic skin repair it may interfere with a cosmetic result. Therefore, unless infection is anticipated because of the circumstances of the lesion or of the operation, the use of topical sulfonamide therapy may be an unnecessary burden. However, its use in cases in which infection may be anticipated, such as in wounds contaminated under field conditions, is now almost obligatory.

THE USE OF SULFONAMIDE
DERIVATIVES

AS A SOLUTION TO THE PROBLEM OF BACTERIAL
CONTAMINATION IN STORED PLASMA

MILAN NOVAK, PH.D., M.D.
CHICAGO

Bacterial contamination has been the most serious obstacle to the preservation of plasma in the liquid state. Several methods have been proposed to minimize the dangers involved in the accidental use of contaminated plasma,¹ but none previously proposed have proved adequate. We have instituted the use of the sulfonamide group of drugs in stored plasma as bacteriostatic and bactericidal agents. In all of my experimental work and in actual routine clinical usage over a two year period the method has been found to be completely satisfactory regardless of the temperature (4 C.-24 C.) or duration of storage. The quantity of the drug necessary to accomplish the purpose in stored plasma is small, so that there are no noteworthy contraindications to its routine use.

The sulfonamide drugs may be used in conjunction with any of the methods of processing plasma now available. However, since the danger of bacterial contamination of plasma is the most serious objection to storing it in the liquid states, the addition of these drugs to such material makes it possible for hospitals to depend on the safety of plasma stored in the fluid form. This method lends itself conveniently to civil and military use. The

expensive and elaborate methods for processing this essential material thus becomes unnecessary in most instances.

SOURCES OF BACTERIAL CONTAMINATION

Regardless of the care used in the collection and handling of blood or plasma, the chances of bacterial contamination are numerous. The facts that bacteria germinate on the average every thirty minutes and that this occurs whenever they are present in a fluid menstruum and that many species grow even at refrigerator temperatures magnify the seriousness of the problem. Since plasma is in the liquid state for a period of time in all the methods proposed for processing it, i. e. before freezing or desiccation or after reconstitution by thawing or redissolving, it is apparent that in these instances favorable circumstances exist for bacterial multiplication. All these procedures involve accidental contamination by organisms in the air and from the cutaneous surface which harbors a multitude of bacteria, many of which are still viable even after the most scrupulous care in the preparation of the cutaneous area prior to phlebotomy. It has been shown that absolute antisepsis of the cutaneous surface is not possible² and that the hypodermic needle in its passage through the skin may carry with it residual bacteria. Furthermore, a transient asymptomatic state of bacteremia does exist in patients from time to time owing to the entrance of intestinal bacteria into the portal system so that, in spite of every possible care, the blood obtained may contain organisms well adapted to this particular environment. The practice of pooling blood samples, in itself a bacteriologically hazardous procedure, makes possible the contamination of large quantities of plasma. One might include the more limited, specialized technic of obtaining blood from placental sources with the obvious sources of contamination involved.

It is true that in most of these instances the bacteria involved are not true pathogens. It must be emphasized, however, that the sources of greatest trouble are saprophytic species. The latter produce pyrogenic and other toxic substances which, when injected directly into the blood stream, produce a maximum deleterious physiologic effect. The kind of organism present, therefore, is less important than the number of bacteria in such material, since a large number implies the presence of reaction-provoking substances. As the original contamination seldom consists of more than a few organisms, it is clear that if they are prevented from multiplying the dangers are largely eliminated. In the use of the sulfonamide derivatives it has been shown that they not only exert this desirable effect but over a period of time actually effect sterilization of contaminated samples.

INADEQUACIES OF STERILITY TESTS

If contamination does occur despite the use of ordinary care in the collection of blood by means of the closed system, the inoculum obviously will be very minute. The manipulations of pooling, centrifuging and transferring plasma present additional possibilities for a minimal contamination. In view of this, random sampling of the material for sterility tests before the organisms have multiplied in the original specimen gives results that are open to question, since the chance of including one of the bacteria in the small sample removed for culture is remote. If the plasma is incubated or

stored for a period of time prior to the conducting of sterility tests, contamination is then easily demonstrated by routine sampling; but the original material must be discarded. It is to be remembered also that the sampling procedure itself is hazardous and may introduce a contaminant into sterile plasma.

Because of these important considerations a bactericidal substance acting on the original chance contaminant is of practical importance. It has been found that the sulfonamide compounds, when incorporated into the citrate solution, solve all the difficulties of contamination from various sources. These drugs exert their bacteriostatic action from the instant the blood is drawn and, over a period of a few days, actually kill the bacteria present. Contaminated plasma is thus actually rendered safe for use. In our experience³ as well as that of others,⁴ merthiolate (sodium ethyl mercurithiosalicylate) has been found to be inadequate for this purpose.

EXPERIMENTAL DATA

Human citrated (0.3 per cent) blood plasma was used in the experiments. Five or 10 cc. quantities were placed into sterile tubes and increasing amounts of the sulfonamide derivative under investigation were added to each successive tube. Final concentrations of the drugs ranged from 0.02 to 0.1 Gm. per hundred cubic centimeters of plasma. Owing to limitations of solubility, the sodium salt of the drug was used whenever indicated. Each tube, as well as a control containing plasma without the compound, was inoculated with 0.1 cc. of a saline dilution of the culture so that the final inoculum was less than 500 organisms per cubic centimeter of plasma. In some instances a larger inoculum was used. With the dilution-plating technic, the number of bacteria introduced into each tube was determined by culturing 0.1 cc. quantities of plasma on nutrient agar. The tubes were then placed in a refrigerator at 4 C. to 6 C. A duplicate set of tubes was allowed to remain at room temperature (20-24 C.). Subsequent periodic enumeration of the bacteria present in each tube was carried out at various intervals of time.

The drugs investigated included sulfanilamide, sulfapyridine, sulfathiazole and sulfadiazine. The bacteria used were in all instances from sources which have an application to the problem in question. One hundred and fourteen strains have been investigated over a two

year period. Twenty-three of these were isolated from stored blood and plasma, and thirty-one were isolated from cutaneous surfaces. The remainder were obtained from air, dust or soil. The organisms from these sources included the following:

Staphylococcus aureus (hemolytic and nonhemolytic).
Staphylococcus albus (hemolytic and nonhemolytic).
Staphylococcus citreus.
Micrococcus (several species).
Streptococcus (beta and alpha hemolytic types).
Pseudomonas aeruginosa.
Bacillus subtilis.
Bacillus cereus.
Bacillus mycoides.
Bacillus sp. (several unidentified species).
Vibrio sp. (unidentified; from the air).

Since it is not practicable to publish the results on all these organisms, the data presented are representative of the type of result obtained on organisms isolated from accidentally contaminated stored plasma or blood. In the tables are recorded the results of periodic enumeration of the bacterial population in various concentrations of the drugs.

SIGNIFICANCE OF EXPERIMENTAL RESULTS

Since only a small portion of my data are reproduced, supplementary comments are necessary in order to present all my evidence. The tables demonstrate the results on the sterilizing effect of the different drugs used. In most instances this was accomplished in three days at room temperature. A longer period was required for the same results to be achieved at refrigerator temperature. Therefore, maintaining contaminated plasma at room temperature for several days would actually be a useful procedure if one of the sulfonamide compounds was added. It is also apparent from table 1 that larger amounts of the drugs are necessary for longer periods of storage when the plasma is maintained at refrigerator temperatures. This is due partly to the decreased activity of the compound and partly to the preservative action of the low temperature on the bacteria.

In exceptional cases, control tubes became sterile owing to the bactericidal action of the plasma itself. This occurred in refrigerated specimens as well as in those maintained at room temperature.

The data show that no one compound is preferable, since the end results are the same. Preliminary results with sulfadiazine indicate that they will parallel those presented herein. They are not included because the period of storage has not been sufficiently protracted.

refrigerator temperatures and were completely inhibited in freshly drawn citrated human blood by 0.02 per cent sulfanilamide at 4 to 6 C. In the interim they were maintained on peptone mediums, acquired an unusual resistance to the bacteriostatic action of the sulfonamide derivatives and lost their ability to grow at refrigerator temperatures. It was found that 0.2 per cent of the sulfonamide derivatives was sufficient to bring about sterilization of plasma inoculated with these strains. It is deemed advisable, therefore, to use 0.2 per cent of the drugs routinely so as to insure complete safety, though it is not known whether similarly resistant strains ever occur as contaminants from the usual sources.

In an original publication⁵ on the use of sulfanilamide for insuring sterility of stored whole blood a 0.02 per cent quantity was recommended for routine use. Hunwicke⁶ has essentially confirmed these results. Since fresh blood contains active phagocytes, complement and bactericidal substances which reinforce the action of the sulfonamide derivative, only a small amount of the latter is required. In plasma larger quantities (0.2 per cent) of the sulfonamide compounds are necessary in the absence of the other antibacterial substances and because of the longer period of storage.

PRACTICAL APPLICATION OF THE METHOD

In actual use it is most convenient to draw blood from the donor directly into a solution containing both sodium citrate and the sulfonamide derivative. The antibacterial effect is thus obtained from the very moment the blood is removed from the donor's vein. For routine work it is advisable to use sodium sulfathiazole.

5. Novak, Milan: Preservation of Stored Blood with Sulfanilamide, J. A. M. A. 113: 2227 (Dec. 16) 1939.
6. Hunwicke, R. F.: Sulfanilamide as a Preservative in Stored Blood, Brit. M. J. 2: 380 (Sept. 21) 1940.

The solution consists of 1.5 Gm. of sodium citrate and 1 Gm. of sodium sulfathiazole sesquihydrate in 50 cc. of physiologic solution of sodium chloride. The solution is autoclaved in the regular flask into which blood is to be drawn. This amount of the sulfonamide drug makes a final concentration of 0.2 per cent when 450 cc. of blood is added. The plasma may then be separated by centrifugation or sedimentation. Whenever tests for sterility are desired they should be made with mediums containing para-amino benzoic acid to neutralize the bacteriostatic action of sulfathiazole, as suggested by Janeway and Shwachman.⁷

SUMMARY

The many advantages in the general use of plasma stored in the fluid state have been overshadowed by numerous reports of bacterial contamination. Another less important objection is the gradual deterioration of prothrombin, fibrinogen and complement. The dangers of contamination by bacteria can be completely eliminated by the addition of 0.2 per cent of sodium sulfathiazole. The objections raised on the basis of deterioration of certain elements are not pertinent, since they are not essential in the instances in which plasma transfusions are ordinarily instituted. In cases of shock, burns, hypoproteinemia and cerebral edema, the elements which deteriorate in stored plasma are of no import. In the majority of instances it is in these conditions that stored plasma is administered, so that the emphasis placed on the deterioration of these elements is not justified from the practical standpoint. In cases of shock with severe hemorrhage, of blood dyscrasias with hemorrhagic tendencies or of infections, the use of fresh blood and plasma rather than stored plasma is most advisable, since erythrocytes as well as the other components are essential to the therapy.⁸

Bacterial contamination, therefore, is the only important problem involved in the storage of fluid plasma. It is my opinion that sulfonamide derivatives, which exert their antibacterial effect under all conditions of processing and storage, make it possible for hospitals and others to rely on the safety and immediate availability of stored liquid plasma. The relatively expensive and elaborate methods for processing this essential material are therefore unnecessary in most instances, as Strumia and McGraw⁹ have already indicated.

CONCLUSIONS

1. Bacterial contamination is the only serious objection to storing plasma in the fluid state.
2. The addition of 0.2 per cent of a sulfonamide derivative, preferably sodium sulfathiazole, in plasma completely eliminates the problem of bacterial contamination, since it actually sterilizes minimally contaminated specimens of plasma regardless of the organism or the temperature involved (4 C. to 24 C.).
3. Plasma preserved with sodium sulfathiazole is safe, immediately available, economical and simple to use.
4. Elaborate and expensive methods for routine processing of plasma are unnecessary in most hospitals.

TREATMENT OF GANGLION BY INJECTION OF CAROID A DANGEROUS PROCEDURE

J. ALBERT KEY, M.D.

ST. LOUIS

In December 1940 a new treatment of ganglion by the injection of a proteolytic enzyme (caroid) was described.¹ The method is as follows:

A suspension of pulverized enzyme in the ratio of 1 drachm of enzyme to each 5 cc. of water is prepared, and 1 minim of hydrochloric acid is added to 10 cc. of suspension. This is shaken vigorously and drawn into a 10 cc. syringe fitted with a 20 gage needle. The needle is inserted and the suspension is injected into the ganglion slowly. Usually 2 cc. is sufficient. In thirty minutes the liquefaction is completed, but the solution may be allowed to remain twenty-four hours without causing any distress and the patient may return the following day for aspiration. The ganglion may then be aspirated freely and the collapsed cyst irrigated with distilled water without removal of the needle. A light pressure dressing is applied.

I have under my care a patient who was treated in this manner and the result is a surgical tragedy. The report of this case is as follows:

REPORT OF CASE

On the evening of Aug. 8, 1941 a woman aged 22 consulted her physician on account of a ganglion on the dorsum of the right wrist which had been present for about four years. Two cc. of the suspension of caroid, as described, was injected into the ganglion. This was followed by immediate severe pain. The pain was excruciating, and efforts to withdraw the material by means of the needle were not successful. Consequently, about half an hour later under aseptic conditions a small stab incision was made into the ganglion and the material was expressed. The patient was sent home with a dry dressing applied to the wrist and given sedation. The next day the

Fig. 1.—The wrist and hand seven days after the injection of caroid. The necrotic skin and subcutaneous tissue have been excised and the hand is moderately swollen. The margins of the wound are undermined.

wrist and forearm were red, hot and swollen, the patient felt sick and the temperature was elevated. The swelling increased rapidly and on the evening of the second day, about forty hours after the original injection, the patient was admitted to the Barnes Hospital.

From the Department of Surgery of the Washington University School of Medicine.

1. Ball, E. J.: A New Treatment of Ganglion. *Am. J. Surg.* 50: 722-723 (Dec.) 1940.

On admission the temperature was 38 C. (100.4 F.) and the pulse was 100 and the patient appeared to be moderately sick. The physical examination was negative with the exception of the right upper extremity, which was much swollen, moderately red and extremely tense, especially over the upper portion of the forearm and around the elbow. The redness and swelling extended up to the shoulder. On the dorsum of the wrist there was a small incision about $\frac{1}{2}$ inch long from which a small amount of thin purulent material could be expressed. Extending downward from this onto the dorsum

Fig. 2.—The forearm, wrist and hand eighteen days after the injection of caroid, showing the undermining of the skin by the necrosis of the subcutaneous tissues.

of the hand was an area of necrosis of the skin which was about 1 inch wide and 3 inches long. The swelling and redness extended up to the shoulder. The arm was so tense that gas bacillus infection was considered. However, there was no odor from the pus, no gas bubbles were expressed from the wound and smears showed a few slender bacilli and a few cocci. Consequently the entire upper extremity was immobilized in a massive hot wet dressing and elevated on two pillows. The patient was given 2 Gm. of sulfathiazole on admission and was given 1 Gm. every four hours afterward.

Laboratory examination showed the urine to be normal, the white blood cell count was 29,950, the differential count was stabs 17 per cent, segmented cells 76 per cent, lymphocytes 12 per cent and monocytes 4 per cent, the red blood cell count was 3,110,000 and hemoglobin was 62 per cent.

On the following morning the swelling and redness had extended above the shoulder and for a moderate distance onto the chest wall. The tenseness and pain in the arm were about the same as on admission. Consequently, under local anesthesia the incision on the dorsum of the wrist was extended upward for a distance of about 2 inches. The area of necrosis on the dorsum of the hand was also incised. After the incision through the skin had been made it was found that the subcutaneous tissues presented a peculiar grayish white gelatinous appearance. Apparently there was widespread necrosis of the subcutaneous tissues, the necrosis extending beyond the limits of the incision, but it was felt that the incision would afford ample drainage. Three Gm. of sulfanilamide was placed in the wound. The hot wet dressing and the sulfathiazole were continued (fig. 1). At this time the temperature was 38.8 C. (101.8 F.) and the pulse was 120. A blood culture which had been taken on admission showed no growth. That afternoon the patient was transfused, 500 cc. of citrated blood being given.

Culture of the wound on the day after admission and also ten days later revealed colon bacilli, bacilli of the subtilis group and *Staphylococcus albus*. No streptococci were found, but the patient entered on Sunday afternoon and the cultures were not made until she had had 5 Gm. of sulfathiazole by mouth.

After the incision and drainage with the continued use of 1 Gm. of sulfathiazole every four hours the patient's general condition improved. The temperature ranged from 37 to 39.2 C. (98.6 to 102.6 F.) until August 17, when it dropped to normal and there was no significant rise in temperature

after that date. The swelling and redness in the upper arm subsided gradually, but the region of the elbow remained swollen and red and tender. Consequently, on August 15 the elbow was aspirated and it was found that most of the swelling was in the subcutaneous tissues, only a few cubic centimeters of serosanguineous fluid being obtained. Cultures of this yielded no growth.

The improvement continued, but there was persistent swelling and tenderness over the dorsum of the forearm and on August 21 a probe was introduced beneath the skin and it was found that there was a cavity extending up almost to the elbow. Under local anesthesia the skin over this cavity was incised and the skin edges were folded back. It was found at this time that the grayish white necrosis of the subcutaneous tissue extended well over the dorsum of the forearm and almost up to the elbow (fig. 2). The wound was dressed with sulfanilamide powder every other day.

In the meantime the extensive area of necrosis on the dorsum of the hand had been excised with a knife. Under it was found a similar gray necrosis of the subcutaneous tissue. The necrosis of the subcutaneous tissue extended beyond that of the skin, so that it involved the tissues on either side to the border of the hand and down to the knuckles. The veins were thrombosed and necrosed. Apparently the necrosis did not extend through the tendon sheaths, nor did it involve the wrist joint. This is partly accounted for by the fact that from the time the patient was admitted to the hospital the hand and wrist were immobilized, first in a large wet dressing, then on a splint and finally in a plaster of paris mold.

On August 17 the patient had urticaria and complained of a sore throat, and on examination the tongue and pharynx were bright red. This was believed to be due to the sulfathiazole, which she was still taking. The sulfathiazole was discontinued, and the urticaria and sore throat cleared up promptly. The wet dressings were discontinued on August 14.

After the incision of the skin over the extensive subcutaneous abscess the wound was dressed daily with sulfathiazole powder and the necrotic tissue was excised or separated. The infection subsided and the convalescence was uneventful.

On September 25 Dr. J. B. Brown operated on the patient and drew the skin together over the forearm and sutured this part of the wound, while that part over the wrist and dorsum of the hand from which the skin and subcutaneous tissue had been lost by necrosis was covered with a split skin graft. This was of necessity applied directly over the sheaths of the extensor tendons. The graft was successful and the patient left the hospital on October 4, fifty-seven days after admission.

At present (Oct. 28, 1941) there is marked disability of the hand, as the fingers are quite stiff and the extensor tendons are adherent to the adjacent tissues.

COMMENT²

This case is reported because it is felt that the medical profession should be warned against the injection of material which is not known to be sterile. I believe that we are apt to forget sometimes how dangerous this can be. It is bad enough to place unsterile material in an open wound, but it is much more dangerous to inject it into the tissues. It is believed that the widespread necrosis was partly chemical from the enzyme and partly due to the bacteria which it contained.

Cultures of the caroid which was used in this instance were made and the material was found to be heavily contaminated with *Escherichia coli*, *Bacillus subtilis*, nonhemolytic streptococci and *Staphylococcus albus*. Two other samples of the material were obtained else-

where and were cultured and, strangely enough, these also were heavily contaminated with the same four organisms.

I have written to the American Ferment Company and in its reply it implies that sterilization is not necessary if the injection is properly and carefully done. This, of course, is an error, as, if the material contains pathogenic organisms, it does not make any difference how the injection is made. One is still implanting pathogenic organisms into the tissues. The firm states that "where the physician desires to employ a sterilized solution" the caroid powder can be sterilized by heating it for twenty to thirty minutes to the temperature of boiling water. Apparently, dry heat is recommended and the firm advises making fresh suspensions in sterile water just before using. It is my impression that this is not adequate sterilization for material which is to be injected and which may or may not contain spore-bearing bacteria. If this material can be sterilized without destroying the enzyme, this should be done before it is sold for injection or implantation in wounds. If it cannot be sterilized completely without destroying the enzyme, it should not be sold for injection or implantation in wounds.

STUDIES ON LYMPHOGRANULOMA VENEREUM INFECTION OF THE RECTUM

WALTER LINCOLN PALMER, M.D., PH.D.

JOSEPH BARNETT KIRSNER, M.D.

AND

ENID C. RODANICHE, PH.D.

CHICAGO

The purpose of this paper is to call attention to the frequency of lymphogranuloma venereum infection of the rectum, to emphasize the rather characteristic clinical and diagnostic features and to comment on the therapeutic value of sulfanilamide and its derivatives.

Lymphogranuloma venereum typically is a subacute, or rather a chronic, venereal disease¹ characterized primarily by the bubo. Spontaneous recovery may occur, or the disease may lapse into a chronic indolent state. The course may be acute, almost typhoidal in character, and, particularly in extragenital infections, its true nature may not be suspected. Generalized

2. Caroid, the preparation of papain (the active principle from the fruit of *Carica papaya*), originally marketed by the American Ferment Company for oral use as a digestive ferment, was rejected by the Council on Pharmacy and Chemistry in 1914 after extensive consideration (Caroid and Essence of Caroid Refused Recognition, *Annual Reprint of the Reports of the Council on Pharmacy and Chemistry*, 1914, p. 109) because the digestive activity of the product on proteins was found to be low and variable by the methods of testing employed at that time.

manifestations, such as fever and multiple arthritis, may be present. There is evidence of the occurrence of a subclinical form. For instance, the husband of our patient E. S. (case 1) has no clinical evidence of disease, gives no history suggestive of such infection and yet has been found, on the two occasions on which he has been tested, to give a strongly positive Frei reaction. His blood serum has been shown to possess neutralizing properties against the virus.²

The great frequency of lymphogranuloma venereum is not generally appreciated. In an extensive study in Cleveland in 1932 in a group of 1,010 patients hospitalized for various disorders found 58 (5.7 per cent) who gave a definitely positive Frei reaction. All of these gave a definite history of lymphogranuloma venereum. Gray and his associates⁴ in 1936, working in a city venereal disease clinic, obtained a positive Frei reaction in 3.4 per cent of the white and in 40 per cent of the Negro

In the female, rectal involvement apparently occurs usually as a direct extension of the disease by way of the lymphatic vessels from the vagina to the rectum. We have not been able to elicit a history of coitus per rectum from our female patients, although this has been reported by other investigators. One of our male patients, however, who had never experienced the heterosexual relationship had frequently practiced pederasty. This is in accord with the view that rectal involvement in the male is frequently due to direct infection.⁶

The outstanding symptom of the disease is rectal bleeding, usually small in amount but recurring daily for months and years. Occasionally the bleeding is rather copious. There is little or no pain until the development of stricture, when abdominal cramps and tenesmus are likely to appear. A seropurulent rectal discharge may be present. Perianal or perirectal abscesses with fistula formation constitute frequent complications.

TABLE 1—*Lymphogranuloma Venereum Infection of the Rectum in Ten White Patients**

Name	Sex	Age	History of Buboes	Lesion	Frei Reaction, Min	Neutralizing Power of Serum	Isolation of Virus	
							Source of Biopsy Specimen	Result
1 E S	♀	40	Positive	Reddened granular mucosa, stricture 4.5 cm above anus	10	Strongly positive	Ulcerated mucosa below stricture	Negative
2 L P	♂	40	...	Friable, bleeding mucosa, colostomy, rectal stricture	12	Positive	Lower margin of stricture	Positive
3 I P	♀	38	Positive	No inflammation, smooth stricture 6.5 cm above anus	13	Very strongly positive	Lower margin of stricture	Positive
4 L C	♀	33	Positive	Inflamed, bleeding, polypoid mucosa, stenosis of anus	12	Strongly positive	Polypoid area of mucosa	Positive
5 G R	♀	26	Positive	Stricture 5 cm above anus; mucosa below chronically inflamed	11	Strongly positive	Lower margin of stricture	Negative
6 M G	♀	28	Positive	Granular, bleeding mucosa, mucopurulent exudate, no stricture	7	Strongly positive	Same, 2½ mo later	Positive
7 T B	♂	30	Negative	Numerous superficial ulcerations with bleeding, no stricture	8	Positive	Rectal mucosa	Negative
8 B S†	♀	40	Negative	Granular, bleeding mucosa, no stricture	8	Positive	Rectal mucosa	Negative
9 C O.	♂	41	Negative	Inflamed, friable, edematous, bleeding mucosa, profuse purulent exudate, no stricture	7	Positive	Rectal mucosa	Positive
10 P H	♀	30	Negative	Bleeding mucosa; benign polypoid stricture 8 cm above anus, colostomy	0; 7	Positive	Mucosa below stricture	Negative
						Positive	Same, 13 mo later	Unsatistactory

* The cases of E. S., L. P., I. P., M. G., T. B. and P. H. have been described in considerable detail in a previous publication (Rodaniche, End C., Kirchner, J. B., and Palmer, W. L. Lymphogranuloma Venereum in Relation to Chronic Ulcerative Colitis, J. A. M. A. 115:51-59 [June 17] 1940). Further information regarding E. S. is included with the case reports appended to this article.

† Died; see text and case summary.

‡ Commercial antigen.

patients. Many of these did not give a positive history. In spite of the latter figure it is clear that the disease is no respecter of race or, indeed, of sex or age. Statistics vary as to the number of cases in which rectal involvement occurs, but D'Aunoy and von Haam⁵ considered the inflammatory stricture of the rectum to be "without doubt the most serious manifestation of venereal lymphogranuloma."

The rectal infection of lymphogranuloma venereum is extremely chronic and, as a statement has been made that while no patient dies from this disease all do, in time, die with it. The inflammation usually leads to the formation of a stricture which may produce complete obstruction. In a series of 76 patients with chronic inflammatory disease of the rectum, the rectosigmoid or the colon seen by us, 10 (13 per cent) were found to have lymphogranuloma venereum. All these patients were white, 7 were female and 3 were male.

Stricture formation is probably a rather late phase of the disease, and yet the diagnosis is rarely made before the stricture develops. It was present in 6 of our 10 cases (table 1). Although the date of the primary infection is usually unknown, the slow development of the lesion is indicated by the fact that the rectal symptoms may develop months or years after the appearance of buboes. The course of the disease is extremely chronic. We have succeeded in demonstrating the presence of virus in the rectal mucosa six, eight, thirteen and twenty-one years after the onset of symptoms. Case 1 illustrates these features beautifully. An interval of ten years elapsed between the development of the bubo and the appearance of rectal bleeding. During a second interval, of eleven years, bleeding continued and the rectal stricture remained essentially unchanged. The virus was then isolated from the rectal mucosa twenty-one years after the original bubo. The persistence throughout this twenty-one year period of a stubborn and moderately severe "rheumatoid arthritis" is of interest.

Lymphogranuloma venereum often produces an almost pathognomonic type of rectal stricture. It has been

recognized under various names in the medical literature for almost a hundred years, first as hyperplastic infiltration of the rectum and later, more appropriately, as inflammatory stricture of the rectum. The stricture is produced by an inflammatory and cicatricial infiltration of the entire circumference of the rectum. It is usually rubberlike in consistency; the examining finger fits into it snugly, as into a tight glove. The mucous membrane covering the stricture is friable and edematous; ulceration, polyposis and fistulas may develop. Torpin, Pund and Sanderson,⁷ after studying 145 cases of lymphogranuloma venereum, said: "All patients with rectal strictures not due to trauma of hemorrhoidectomy have had a positive Frei test." However, we have observed at least 3 cases of so-called nonspecific ulcerative colitis involving the entire colon with rectal or sigmoidal stricture. There was no history of lymphogranuloma venereum in any of these, the Frei reaction was negative and the serum did not contain neutralizing bodies for lymphogranuloma venereum. Szilagyi⁸ noted a positive Frei reaction in 14 of 17 patients with rectal stricture, excluded 2 of the remaining 3 as unsatisfactorily examined and attributed the stricture in the third to syphilis because there was "a negative Frei reaction, a positive Kahn test and a positive rectal biopsy for lues. At autopsy the luetic etiology of the stricture was confirmed and other evidences of lues were found."

The stricture is located usually 3 to 8 cm. above the anus, although it may extend into the sigmoid flexure. In 1 of our patients (P. H.) there were two strictures, one in the rectum and one in the midportion of the sigmoid flexure. Another patient (L. P.) had been operated on elsewhere for a benign inflammatory stricture of the transverse colon. The pathologist had described the lesion in the resected specimen as "unusual." When the patient was seen by us some time later a rectal stricture was present and the Frei reaction was strongly positive. Rendich and Poppel⁹ and other investigators have described similar cases.

The rectal mucosa in the 4 patients without stricture was friable, edematous and indistinguishable proctoscopically from that of patients with nonspecific ulcerative colitis. If the validity of the diagnosis under the foregoing circumstances is questioned, reference may be made to case 5 (C. C., table 1), in which there was no history of buboes and no stricture; pederasty had been practiced; the Frei intracutaneous test gave a positive result on three occasions; the patient's serum was shown to contain antibodies capable of neutralizing the lymphogranuloma venereum virus, and the presence of the virus in the rectal mucosa was demonstrated by animal inoculation.

The question arises as to whether lymphogranuloma venereum is capable of producing acute fulminating ulcerative colitis. In 1 of our 10 cases death occurred. It was not possible to decide whether the lesion of the colon was due to lymphogranuloma venereum, to nonspecific ulcerative colitis or to both diseases. The patient (B. S.) gave no history of buboes, had undergone hemorrhoidectomy for rectal bleeding eighteen months before death, had diarrhea a year later and died after an acute illness with fever and diarrhea of six months' duration. The distal two thirds of the colon

was extensively ulcerated, the appearance being considered typical of nonspecific ulcerative colitis. It is unusual, however, in our experience for patients to die of ulcerative colitis without involvement of the entire colon. The Frei and the virus neutralization test had both given strongly positive results. An attempt to isolate the virus from a biopsy specimen of the mucosa was not successful, and unfortunately no further attempt was made at autopsy. To the best of our knowledge, no identical picture has been described in the literature on lymphogranuloma venereum, although Falconer¹⁰ described a somewhat similar but also inconclusive case. The acute febrile course is well recognized. Furthermore, there is no reason to expect the infection to remain localized in the rectum. Indeed, definite evidence of involvement of other portions of the colon has been cited previously in this paper. Lombart and Mañeru¹¹ have described a patient with a positive Frei reaction, a rectal stricture and multiple strictures of the ileum attributed by them to lymphogranuloma venereum. The attempt, however, to relate regional ileitis in all cases to lymphogranuloma venereum has not been successful. In 4 cases of regional enteritis studied by us the Frei reaction has been negative and attempts to isolate the virus from the diseased tissue or from a

TABLE 2.—Protection of Mice with Sulfanilamide and Sulfanilylguanidine Against the Lymphogranuloma Venereum Virus

Drug in Diet	Number of Mice	Percentage

neighboring lymph gland, obtained at operation, have been unsuccessful.

The diagnosis of the genitoanorectal syndrome of lymphogranuloma venereum is simple if the possibility is kept in mind. Unfortunately, there exists an impression that it is to be found only in persons plying the oldest of all professions and in persons having intercourse with them. As a matter of fact, lymphogranuloma venereum, like all other venereal diseases, is fairly widely disseminated throughout the United States and, indeed, throughout the world. The most characteristic lesion, of course, is the unilateral or bilateral suppurating or nonsuppurating inguinal adenopathy, the bubo. The bubo is almost pathognomonic of lymphogranuloma venereum. Consequently the history of such a lesion or the residual scar is presumptive evidence of the disease. In our 10 cases, such a history was present in 6 and absent in 4 (table 1). A history of buboes is thus seen to be important but not essential. Esthiomene or genital elephantiasis, while not occurring in our series, would render the diagnosis self evident.

In our series the Frei reaction has been uniformly, consistently and persistently positive. We have used a mouse brain antigen prepared by one of us (E. C. R.) according to the usual technique from a strain of the virus isolated from pus aspirated from the enlarged inguinal node of a patient in the third week of the infection. Control tests have been performed regularly to exclude

sensitivity to mouse brain without virus. In some cases tests have also been made with human antigen and with chick embryo antigen (lygranum).¹² The validity of the positive Frei reaction has been confirmed in all our 10 cases by a positive virus neutralization reaction and in 5 by isolation of the virus itself. In no instance

have we been confronted with a definitely positive Frei reaction without confirmatory evidence, such as a positive virus neutralization reaction. Furthermore, the validity of 66 negative Frei reactions has been substantiated by negative virus neutralization reactions.

In 1 of our 10 patients (M. G.) the cutaneous reactions, with both the mouse and the human antigen, were marginal in size, measuring respectively 7 and 5 mm. in diameter. The validity of the test was proved, however, by the demonstration in the serum of a strong neutralizing property for the virus. Pseudoreactions, consisting of allergic responses to mouse brain protein, have been eliminated by repetition of the test with human or chick embryo antigen. In addition to the 66 patients with nonspecific ulcerative colitis previously mentioned as having a negative Frei reaction we have studied a control group of 40 patients with diverse disorders such as peptic ulcer or carcinoma. All had a negative Frei reaction. We have come, therefore, to regard the Frei reaction as highly specific.

The virus neutralization test, previously described by one of us (E. C. R.),² is reliable but not as simple to perform or as inexpensive as the Frei test.

The most conclusive diagnostic procedure is the isolation of the virus from biopsy specimens of the rectal mucosa. The bits of tissue are well washed with sterile salt solution, macerated and suspended in salt solution, and the suspension is injected intracerebrally into mice. Typical symptoms occur in two to eight days. These consist of ruffling of the fur, arching of the back, tremors, ataxia, priapism, conjunctivitis, convulsions, cachexia and occasionally paralysis. Death ensues in about 50 per cent of the inoculated animals. The virus may be isolated from the brain; it may be transmitted from animal to animal, the virulence of the strain deter-

mined and the identity of the virus demonstrated by cross immunization experiments. These procedures are obviously more laborious than the Frei test, and negative results are less significant. However, in our series the virus was isolated before treatment in five of seven attempts in 5 cases. The identity of the five different strains of the virus thus obtained was established by cross immunization experiments.¹³ As a further control, eight attempts were made to isolate the virus from the rectal mucosa obtained for biopsy from 7 patients with nonspecific ulcerative colitis who had a negative Frei reaction. These were uniformly unsuccessful.

The differential diagnosis of lymphogranuloma venereum infection of the rectum is thus not difficult. The stricture itself is a characteristic lesion not readily confused with carcinoma. Other inflammatory conditions of the rectum, such as nonspecific ulcerative colitis, may lead to the formation of stricture, but the presence of a positive Frei reaction, with or without a history of buboes, is presumptive evidence that the rectal lesion is attributable to lymphogranuloma venereum. The coexistence of gonorrhea or syphilis or both should not confuse the issue. Gonorrheal proctitis does occur, but there is reason to doubt that gonorrhea ever invades the rectal tissue deeply enough to produce an "inflammatory stricture." The possibility of syphilitic proctitis must be considered, but this lesion appears to be rare. Indeed, in the light of our present knowledge of lymphogranuloma venereum, its very existence would be questioned if it were not for the case described by Szilagyi.⁸

TABLE 4.—Summary of C. C.'s Case History

Date	Therapy	Frei Reaction	Virus Isolation	Rectum
10/1/40		+	.	Edematous, friable, bleeding, purulent discharge
10/22		..	+	Unchanged
10/31 to 11/19	Sulfanilamide, 2 1/2 to 3 1/2 Gm daily		0	Mucosa entirely normal
11/19		..	+	
11/20-30		Friable, bleeding, mucopurulent exudate
11/20		.	..	
12/1-6	Sulfanilamide, retention enema daily, 2 1/2 Gm in 250 cc. of water			
12/7-4/5	Sulfanilamide retention enema 3 times weekly			
1/7/41	Sulfanilamide retention enema 3 times weekly	..		Definitely better; slight bleeding; mucosa no longer friable
2/3	Sulfanilamide retention enema 3 times weekly			Almost normal, few scattered areas of bleeding, no exudate
3/4	Sulfanilamide retention enema 3 times weekly	+	(Ly granum)	Practically normal
4/1	Sulfanilamide retention enema 3 times weekly		0	Slightly granular; practically normal
4/8	Sulfanilamide discontinued			
5/29		.	0	Several small bleeding areas but rectum practically normal

A complete discussion of the therapy of lymphogranuloma venereum is beyond the scope of this paper. However, we do wish to refer briefly to certain experimental studies and clinical observations bearing on the action of sulfanilamide and its derivatives. Numerous workers have described the successful treatment with

12 Grace, A. W.; Rake, Geoffrey, and Shafer, M. F. A New Material (Lygranum) for Performance of the Frei Test for Lymphogranuloma Venereum, *Proc Soc Exper Biol & Med* 45: 259-263 (Oct) 1940.

13 Rodaniche, Enid C. A Comparison of Seven Strains of the Virus of Lymphogranuloma Venereum, *J Infect Dis* 69: 13-149 (Sept) 1941.

these drugs of experimental meningoencephalitis produced in mice and of inguinal buboes produced in other animals by the lymphogranuloma venereum virus.¹⁴ One of us (E. C. R.¹⁵) has found that mice may be protected completely from lethal doses injected intracerebrally by the administration of a diet containing 1 per cent sulfanilamide or 1 per cent sulfanilylguanidine (table 2). The control animals all showed typical meningoencephalitic symptoms, usually within ten days, and 50 per cent of them died within that period. The protected animals remained well during the ten days of drug therapy. A few of the animals treated with sulfanilamide had mild symptoms after the discontinuance of the drug, but all recovered. These animals were subsequently found, by reinoculation, to have developed a complete immunity to the virus. The mechanism of this immunity was studied by killing certain infected asymptomatic mice during a period of therapy and assaying the brain. The virus was recovered in high concentration in each instance, indicating, therefore, that although the chemotherapy had protected the animal from disease it had not accomplished an *in vivo* sterilization or an attenuation of the virus.

The foregoing experimental observations on the effect of sulfanilamide and its derivatives are in accord with our clinical experiences and, indeed, with those of other workers.¹⁶

In many respects the most interesting of our group is patient E. S. (table 3), from whose rectal mucosa the virus was recovered twenty-one years after the bubo and whose rectal disease is known to have been present for eleven years. To our surprise, the rectal inflammation subsided entirely and the stricture disappeared almost completely after (1) sulfanilamide and azosulfanilamide and (2) pregnancy, an event which in itself, occurring after twenty years of sterility, was somewhat surprising. The improvement appeared to have been initiated by the chemotherapy and to have been furthered enormously by the pregnancy.

In patient C. C. (table 4) the administration of sulfanilamide for twenty days seemed to produce a most striking transformation in the proctoscopic appearance. The disease process recurred, however, within a week after the discontinuance of the drug. The use of sulfanilamide retention enemas daily for six days followed by such enemas three times weekly for four months apparently resulted in complete healing of the proctitis. The disease has not recurred as yet after seven weeks.

In contrast to the first 2 patients, patient M. G., whose disease was of three years' duration and was unaccompanied by stricture formation, exhibited only slight improvement after the administration of 4 Gm. of sulfanilamide daily for two weeks and no improvement after receiving 3.3 Gm. of azosulfanilamide daily for twenty-seven days followed by 5.3 Gm. daily for fourteen days.

To another patient, G. R. (table 6), whose disease had been present for six years and had resulted in severe stricture formation, sulfanilylguanidine was administered almost continuously for more than two and one-half months in a dose of 10 Gm. daily. Improvement occurred slowly but nevertheless defi-

nately. There was a gain in weight amounting to 11 pounds (5 Kg.). The rectal pain disappeared. The number of stools decreased from fifteen to thirty daily to two to eight daily. The bloody rectal discharge disappeared. The stricture remained about 4 mm. in diameter, but it seemed softer. The adjacent rectal wall became thin and pliable. The mucosa at the site of the stricture and below remained granular and bled easily. The bacterial count per gram of feces decreased from an average of 20 to 50 million organisms, predominantly gram-negative bacilli, to an average of 100 to 600 thousand, predominantly gram-positive cocci.

TABLE 6.—Summary of G. R.'s Case History

Date	Therapy	Frei Reaction	Virus Isolation	Rectum
11/19/40	+	0	Chronic inflammation with stricture 5 cm above anus
2/4/41		..	+	Unchanged
3/4		.. (+ Lys- granum)	..	Unchanged
3/9/40	Sulfanilylguanidine, 10 Gm. daily			
3/18	Little change
3/24	Sulfanilylguanidine, 10 Gm. daily resumed			
3/27	Sulfanilylguanidine, 10 Gm. daily continued	Unchanged
4/8	Sulfanilylguanidine, 10 Gm. daily, continued	+	0	Mucosa bleeding; stricture unchanged
4/22	Sulfanilylguanidine, 10 Gm. daily, continued	..	0	Less bleeding; slightly improved
5/6	Sulfanilylguanidine, 10 Gm. daily continued	.	0	Unchanged
5/13	Sulfanilylguanidine, 10 Gm. daily, continued	..	0	No bleeding; definitely better but stricture unchanged
6/2	Sulfanilylguanidine discontinued			

As yet we have not succeeded in isolating the virus of lymphogranuloma venereum from the rectal mucosa during or, indeed, after chemotherapy. The Frei reaction, however, has consistently remained positive, indicating presumably the persistence of the virus within the organism. Judging from the experimental and clinical evidence sulfanilamide and its derivatives are apparently unable to destroy all the virus in the body, but they do tend to inhibit its action in some unknown manner. It is not clear whether these drugs are merely virustatic or actually virucidal or whether some other mechanism is operative. Perhaps the complete destruction of the virus *in vivo* is prevented by its localization within the cell. Regardless of the mechanism of action, however, the therapeutic value of sulfanilamide and its derivatives seems definitely established.

CONCLUSIONS

1. Lymphogranuloma venereum is a common cause of proctitis and sigmoiditis, with or without stricture formation. Its course may be extremely chronic. The disease may simulate nonspecific ulcerative colitis.

2. The presence of lymphogranuloma venereum may be easily established by means of the Frei intracutaneous test provided the test is properly used and controlled.

3. Therapy with sulfanilamide and sulfanilylguanidine is of definite value, particularly in cases in which there is no stricture formation, but prolonged administration of the drugs may be necessary.

REPORT OF CASES

CASE 1.—E. S., a white woman born in 1900, was first seen by us in 1931. Her childhood had been normal, and she had been perfectly well until after her first marriage, in 1916. She had one child by this marriage, born in 1917. In 1918, when the baby was about a year old, she had a rather severe attack of "rheumatic fever." In 1918 or 1919 her husband left her. The patient had a rather profuse vaginal discharge at some time during this marriage and took daily douches for an indefinite period. She was unable to state whether the vaginal discharge appeared before the attack of "rheumatic fever." Although the discharge was sufficient to make the patient feel that she had contracted a venereal disease, a physician was not consulted. In time the discharge disappeared. In 1919 she had a swelling of the right inguinal lymph node, which was lanced by a physician.

The patient remarried in 1921. She denies having had sexual intercourse with any one other than her two husbands. The arthritis continued to cause her a good deal of trouble. In the course of time it involved nearly all her joints—fingers, elbows, shoulders, back, hips, knees and toes—without causing much deformity. The tonsils and the teeth were removed and various medications given without noticeable improvement. In 1930 she first noticed blood in the stool; this continued to appear until her admission to the hospital. Examination at this time disclosed a deep scar in the right inguinal region and a stricture of the rectum beginning just within the anus.

There was no significant change in the course of the arthritis or in the rectal stricture until November 1939. A biopsy of the rectal mucosa on June 6, 1939 failed to demonstrate the presence of the virus of lymphogranuloma venereum, but on November 10 the virus was successfully isolated. The repeated making of cultures and direct examinations of the stool during the nine years had shown no pathogenic parasites or bacteria except *Bacterium necrophorum*. On November 10 4 Gm. of sulfanilamide daily was prescribed, and medication was continued for ten days, when a rash appeared and the drug was discontinued. The patient reported that she felt "better than in a long time" and that the bleeding had ceased. Azosulfamide was then prescribed in doses of 3.3 Gm. daily, and medication was continued for eight days. The blood in the stools did not recur. Proctoscopic examinations during December 1939 and January and February 1940 revealed a gradual subsidence of the inflammation. By March 1940 the patient was having only one or two formed stools daily without blood. The Frei reaction continued to be strongly positive. At this time, nineteen years after her second marriage, the patient became pregnant. Her condition improved progressively, and there was no further bleeding from the bowel. In July 1940 examination revealed the stricture to be still present, with evidence of mild inflammation of the mucosa. The patient continued free of symptoms and on December 17 gave birth to a normal infant, whose Frei reaction was negative.

To May 1941 there has been no recurrence of the bleeding or of the arthritis, and the patient has remained well. Proctoscopic examination now discloses a thin, atrophic scar, with slight stricture formation about 2 cm. above the anus. The large proctoscope, 1.7 cm. in diameter, may be introduced without difficulty 22 cm. beyond the anus. The mucosa everywhere appears normal except for the scars mentioned. Two pieces of tissue were removed for biopsy in an unsuccessful attempt to demonstrate the presence of the virus. The patient attributes her recovery to the pregnancy, although the record suggests that it began with the administration of sulfanilamide and azosulfamide in November 1939. The Frei reaction is still strongly positive. The patient's husband, who gave a history of having had gonorrhea with complete recovery in 1916, before he met his wife, and who has never had buboes or any clinical symptoms suggestive of lymphogranuloma venereum, nevertheless gave a strongly positive Frei reaction on Nov. 30, 1940 and again on May 19, 1941.

CASE 4.—L. C., a white woman aged 33, had swollen inguinal lymph nodes shortly after marriage, eight years before admission. These nodes suppurated and were lanced by a local physician; draining sinuses persisted for several weeks. A year

later the stools suddenly became loose and watery, and they persisted so for two weeks; examination of the stools for parasites was said to have given negative results. The diarrhea recurred subsequently on numerous occasions, and blood and mucus were noted in the stools. It was said that six months before admission a rectal stricture had been dilated by a proctologist and that polyps had been removed from the rectum one month before admission. On physical examination the patient was seen to be severely emaciated. The anal region was reddened and excoriated; the anal ring was narrowed; the rectal mucosa appeared polypoid and inflamed. Examination of the stools for parasites, agglutination tests (typhoid, paratyphoid A and B, brucellosis) and two Wassermann and Kahn tests gave negative results. *Bacterium necrophorum* was absent from several stool cultures. Roentgenograms revealed active bilateral pulmonary tuberculosis and an extensive lesion involving the rectal ampulla, the nature of which was not determined. The Frei reaction was positive, and the lymphogranuloma venereum virus was obtained from a biopsy specimen of the rectal mucosa. Injection of tissue from the anal region into a guinea pig on three separate occasions revealed no evidence of tuberculosis. There was persistent secondary anemia. The value for total proteins was normal, but the albumin-globulin ratio was reversed. The patient was given sulfanilamide on the eighteenth hospital day in doses averaging about 5 Gm. daily, receiving a total of 68.7 Gm. in thirteen days. The level of free sulfanilamide in the blood rose to 10 mg. per hundred cubic centimeters. There was no definite clinical improvement, however, and the drug was withdrawn because of anorexia, cyanosis and a decrease in the red cell level. Subsequent therapy included several blood transfusions and the administration of sedatives, codeine and vitamins. The number of stools diminished from four to eight daily to two or three, and the inflammation of the rectal mucosa subsided. On the seventy-eighth hospital day the patient was given sulfanilylguanidine, 4.8 Gm.; this dose was used for six days, then 9.6 Gm. for three days, and then 2.4 Gm. for one day, a total of 60 Gm. in ten days. The level of free sulfanilylguanidine in the blood varied from 0.8 to 1.3 mg. and the level of total sulfanilylguanidine from 1.3 to 1.8 mg. per hundred cubic centimeters. The patient's condition remained unimproved, although the total bacterial count in the stool decreased.

CASE 5.—G. R., a white woman aged 26, first noted the passage of blood and pus from the rectum six years before admission. Her appetite gradually had failed, resulting in a progressive loss of weight amounting to 66 pounds (29.9 Kg.). She had undergone two operations for a rectal fistula and had been told of the presence of a rectal stricture. It was learned that at the age of 15 the patient had contracted syphilis and had received antisyphilitic therapy for five years. Marriage had been contracted at the age of 16 and had been terminated at the age of 20, approximately coincident with the development of the rectal bleeding. The patient denied having had sexual intercourse during the six years after divorce.

Physical examination revealed that the patient was thin and obviously ill. There were generalized abdominal tenderness and enlargement of the inguinal lymph nodes. Just to the right of the fourchette was a hard, tender, nodular mass, 2 by 2 cm., in the center of which was a small opening; a broad linear scar was noted on the left side of the fourchette. Proctoscopic examination revealed a stricture 5 cm. from the anus; the rectal mucosa was roughened and granular and bled easily. The Frei reaction was positive; the virus was not obtained from a biopsy specimen of rectal tissue, but it was found at a second examination several months later. The Wassermann and Kahn reactions were negative; the stools at first showed no parasites but later were observed to contain *Strongyloides stercoralis*. *Bacterium necrophorum* was not isolated from stool cultures. Routine agglutination tests gave negative results. There was moderate secondary anemia. Roentgen examination revealed a uniform narrowing and ulceration of the rectum and of the rectosigmoid portion of the colon, with dilatation of the bowel above this narrowing. Roentgenograms of the chest disclosed bilateral fibrocalcific pulmonary tuberculosis. Therapy included the use of a bland diet, sedatives, codeine.

ferrous sulfate, vitamins and a blood transfusion. The clinical condition was not greatly altered. The stools continued to be liquid and contained blood. The patient's temperature at first fluctuated between 98.6 and 100.5 F., gradually rose to 103 F. and then subsided to the previous level. Sulfanilylguanidine therapy was started on the seventh hospital day with a dose of 10 Gm. daily, the patient receiving a total of 106 Gm. in eleven days. The drug was withdrawn for four days because of a localized cutaneous rash; therapy was then resumed for sixty-nine days. The total intake was 800 Gm. The level of free sulfanilylguanidine in the blood gradually rose from 1.5 to 6.8 mg. and the level of total sulfanilylguanidine from 2.1 to 8 mg. per hundred cubic centimeters. There was a decided decrease in the total bacterial count of the stools but not a sterilization.

Improvement occurred slowly but nevertheless definitely. There has been a gain in weight amounting to 11 pounds (5 Kg.). The rectal pain has disappeared. The number of stools has decreased from fifteen to thirty daily to two to eight. The bloody rectal discharge has disappeared. The stricture remains about 4 mm. in diameter, but it seems softer. The adjacent rectal wall is now thin and pliable. The mucosa at the site of the stricture and below it is still granular and bleeds easily. There have been no toxic manifestations from the sulfanilylguanidine therapy, and the red blood count has varied from 4.5 to 5.1 million. Two Frei tests (one with lygranum and one with mouse antigen) during the course of treatment gave positive results. Virus studies were made on two occasions during this period, two and three bits of rectal tissue being removed each time, with negative results.

CASE 8.—B. S., a white woman aged 49, had undergone a hemorrhoidectomy one year and a half previously because of rectal bleeding. Six months prior to her initial visit at the University of Chicago Clinics she had begun to have diarrhea, with blood and mucus in the stools. Proctoscopic examination revealed that the rectal mucosa was granular and bleeding. Laboratory studies, including agglutination tests, examination of the stools for parasites and Wassermann and Kahn tests gave negative results. The Frei reaction was positive, but the virus could not be isolated from a biopsy specimen of the rectal mucosa. The patient's condition did not improve on treatment which included the use of a bland diet, sedatives and cod liver oil retention enemas, and she was admitted to the hospital. Her condition grew progressively worse. The diarrhea, producing numerous watery stools giving a strongly positive chemical reaction for blood, increased. The patient's temperature at first varied from 99 to 102.5 F., gradually rose to 104 F. and by the twenty-first hospital day had increased to 106 F. The white blood cell count decreased from 11,400 to 2,550. There was severe abdominal distention necessitating the use of continuous Wangenstein suction. Despite the administration of five blood transfusions and of large quantities of fluids parenterally the patient died on the twenty-second hospital day. Necropsy disclosed nonspecific ulcerative colitis with fibrinous peritonitis, pulmonary embolism with infarction of the right lower pulmonary lobe, dilatation of the right auricle and ventricle, anasarea and bilateral hydrothorax.

CASE 9.—C. C., a man aged 41, an unemployed salesman, entered the University of Chicago Clinics because of a purulent rectal discharge of three years' duration. He had undergone an operation for fistula in ano six months previously. He gave a history of having participated for many years in extra-genital intercourse (pederasty), in which he had frequently assumed the feminine role. He denied having indulged in this practice for the past five years. There was no history of buboes or enlarged inguinal nodes. Proctoscopic examination disclosed the presence of a purulent exudate in the rectum and the sigmoid flexure; the rectal mucosa was friable and bled easily. Hospitalization was necessitated by the development of cardiac failure secondary to coronary occlusion.

The Frei reaction was positive, and the lymphogranuloma venereum virus was recovered from several biopsy specimens of the rectal mucosa. Sulfanilamide therapy, begun on the thirty-first hospital day with doses of 2.4 to 3.5 Gm. daily, was continued until a total of 73 Gm. had been administered in

twenty days. The level of free sulfanilamide in the blood rose to a peak of 13.5 mg. per hundred cubic centimeters. The inflammatory process gradually subsided, and at the termination of therapy the rectal mucosa appeared proctoscopically to be practically normal. The Frei reaction continued to be positive. Attempts to isolate the virus from several biopsy specimens of the rectal mucosa at this time were unsuccessful. The rectal inflammation recurred within a week after the discontinuance of sulfanilamide. It was not deemed advisable to resume sulfanilamide therapy in the dose previously given because moderate anemia had developed. Consequently, the patient was given nightly retention enemas containing 2.4 Gm. of sulfanilamide dissolved in 250 cc. of warm water. The rectal discharge again decreased, and the mucosal inflammation subsided. The retention enemas were given three times each week for the next four months. The patient continued to improve; the bowel movements decreased to one or two formed stools daily, the rectal discharge disappeared and proctoscopy revealed the mucosa to be almost normal in appearance. A Frei test done during the course of this treatment gave a positive result; on two occasions the virus was not obtained from several biopsy specimens of rectal tissue. The sulfanilamide retention enemas were discontinued after four months. To date, two months later, the rectal mucosa continues to present only a slightly granular appearance and the patient's clinical condition remains satisfactory.

950 East Fifty-Ninth Street.

ABSTRACT OF DISCUSSION

DR. HERBERT T. HAYES, Houston, Texas: My associates and I have had experience with lymphopathia venereum for many years but have always been disheartened by the results of treatment. We have found the incidence of lymphopathia venereum much more frequent in the Negro race. We rarely see a stricture case in private practice. Negroes and especially Negro women make somewhat of an economic problem in almost any Southern city, because after they have had these strictures a good number of years most of them are partial invalids. I agree with the authors that gonorrhea and syphilis should not be considered a causative factor except in rare instances. Before we become aware of the existence of lymphopathia venereum we thought that gonorrhea was the probable causative agent because of its frequency in the rectal smears. Trauma, however, of an inflamed mucosa may at times set up an inflammatory process that will result in a stricture. I agree with the authors' observations on the use of sulfanilamide. We have found it has lessened the discharge, reduced the infection and made the patients feel better. We have observed spectacular results and an apparent cure in 2 cases of early infection of the rectum without definite stricture formation or in what we have frequently referred to as the prestricture stage. In the extremely bad cases I still advocate a colostomy. Patients who have had a colostomy and still have constitutional symptoms, such as anemia, arthritis and any of the sequelae that go with chronic infection, should have a resection of the rectum. Colostomy alone rehabilitates many of these patients. Those who are scar formers are the ones who are most likely to have trouble with lymphopathia venereum, and that is why the Negro race is so susceptible.

DR. MOSES PAULSON, Baltimore: Dr. Palmer and his associates have shown that bowel involvement due to the virus of lymphogranuloma venereum is not restricted to the Negro race, that it is more frequent than is generally appreciated, that at times it is indistinguishable from nonspecific ulcerative colitis and that by the demonstration of virus in intestinal material this disease can be separated from ulcerative colitis, thus delimiting ulcerative colitis and offering another approach to the former. These observations tend to clarify some obscure bowel disorders, and they are confirmatory of my researches in this field, reported between 1936 and 1939. The most conclusive diagnostic procedure is in the isolation of the virus from the involved tissue. Dr. Palmer's method differs only slightly from that of my bowel antigen method. A positive Frei test in one with colitis cannot be taken in itself to diagnose lymphogranuloma venereum colitis because it has definite limitations. The

positive Frei reaction may be produced by an unrelated virus infection antedating, coinciding or postdating the colitis, or by a healed virus infection. The same limitations apply to the neutralization test referred to by Dr. Palmer. There is one situation either ignored or not generally appreciated—that of anergy: a few who harbor this virus and never manifest a positive Frei reaction and those who give no Frei reaction while the involvement is either decidedly acute or severely chronic. Particularly in these groups is the detection of the virus in the bowel involvement by my bowel antigen or Dr. Palmer's method important. I have seen no true fibrotic stricture vanish regardless of the nature of therapy. I have found that the use of sulfonamide derivatives has not infrequently reduced the activity of the process, possibly by diminishing secondary infection.

DR. ARTHUR W. GRACE, New York: We have been studying lymphogranuloma venereum for nine years at the New York Hospital and have observed that the anal variety of the disease occurs two and a half times as frequently as the inguinal variety and is therefore the commonest of the symptomatic varieties. We have been using the sulfonamide derivatives successfully for the treatment of lymphogranuloma venereum since 1938 and have employed sulfanilamide, sulfathiazole and sulfaguanidine. Sulfathiazole has given the best therapeutic results with the least toxic reaction. It is administered in a dose of 1.5 Gm. three times a day for two to three weeks, followed by 1 Gm. three times a day for another three weeks. This regimen is sufficient to cure all the cases of the inguinal variety of the disease which we have treated. Cases of proctitis without stricture, the earliest manifestation of the anorectal variety of lymphogranuloma venereum, also yield readily to such treatment. The advent of stricture extends the duration of treatment of proctitis to as long as six or twelve months. In these cases several courses of sulfathiazole therapy are given with rest periods of one or two weeks between courses. In over 90 per cent of all cases of the anorectal variety of lymphogranuloma venereum the proctitis is cured or improved by the use of sulfathiazole. Fibrous strictures are unaffected. In their use of mice for evaluating the effect of drugs in the treatment of lymphogranuloma venereum in man, Dr. Palmer and his collaborators administered the drug orally. While performing similar experiments several years ago we noted that the mice did not always consume all of the material offered. By injecting a solution of the drug intraperitoneally, results were obtained similar to those of the authors. For the past four years we have been examining cases of ulcerative colitis first with the Frei test and later with the complement fixation test for lymphogranuloma venereum. No positive reaction has yet been obtained by the use of either test.

DR. ZACHARIAS BERCOVITZ, New York: It seems to me that the main value of this discussion is to direct attention to the fact that there are cases of ulcerative colitis in which the Frei test will be found to be positive. We have had that experience in our clinic at the New York Postgraduate Hospital. The Frei test is specific. It is valuable because it helps us to separate from the group of so-called nonspecific ulcerative colitis those whom we can treat specifically. Thus we can help more patients. With the rectal type of stricture we have found that Frei antigen in small doses, 0.1 cc. subcutaneously over a period of eighteen months to two years, has caused complete relaxation of the strictures and, when prior to the injection of the antigen we were unable to pass even a small finger into the rectum, at the end of that time we were able to examine with the standard size sigmoidoscope and find an essentially normal mucosa.

DR. H. F. SAWYER, Detroit: I wish to substantiate the findings in our clinic of those of the authors and the discussers. I particularly would like to ask Dr. Palmer what effect sulfanilamide has had on the extrarectal lesions. I myself have not seen any appreciable benefits.

DR. WALTER L. PALMER, Chicago: I was glad that Dr. Hayes brought out the great incidence of the disease, particularly the anorectal syndrome, in the Negro race. There is no doubt that it is much more frequent in them than in the white race. We wished to emphasize, however, that it does occur not infrequently in the white race. Dr. Paulson raises two questions: first, whether or not the presence of a positive Frei reaction proves that the lesion in the colon is lymphogranuloma venereum.

Of course it doesn't. The positive Frei reaction proves only that the patient has or has had—and we are inclined to think it means he still has—lymphogranuloma venereum. It does not prove the nature of the rectal lesion. With regard to negative Frei reactions, Dr. Paulson is quite right. It is possible for lymphogranuloma venereum to be present with a negative Frei reaction. It is, however, foreign to our experience. I was much interested in the remarks of Dr. Grace with regard to the relative incidence of the inguinal and anorectal varieties of lymphogranuloma. We have had no experience with the extrarectal infections and we have not tried sulfathiazole.

OPPORTUNITIES FOR POSTGRADUATE STUDY FOR NEGRO PRACTICING PHYSICIANS IN THE SOUTH

PAUL B. CORNELLY, M.D., DR.P.H.

Associate Professor of Public Health, Howard University
College of Medicine

WASHINGTON, D. C.

There has been an increasing acknowledgment during the past thirty years of the need for keeping the general practitioners of this country abreast of medical advances so that there will not be too wide a hiatus between the development of new principles and techniques and their actual application. This concern has been manifested by the American Medical Association since 1913 through its Council on Medical Education and culminated in a comprehensive study¹ of the educational programs of every state during the years 1937 to 1940. This need has also been emphasized by the Commission on Graduate Medical Education in its recent report,² and just recently the executive committee of the National Board of Medical Examiners has appointed a committee to study the question as to the best method of providing some kind of recognition for the progressive, up to date, efficient and well trained general practitioner.³

Even though such interest has been manifested by these organizations and by many medical schools and medical societies, practicing physicians have not apparently been too concerned about improving themselves. This is true for both Negro and white groups. The 1938 report of the Council on Medical Education and Hospitals of the American Medical Association⁴ stated that in twelve states with fairly accurate records only 25 per cent of the practicing physicians engaged in some form of graduate work during the year. In a study⁵ of five hundred and twenty-five Negro physicians, it was shown that only 40 per cent had engaged in such activities during a ten year period. This certainly shows a deplorable situation.

Many may be the reasons for this apparent indifference on the part of physicians, but the lack of available opportunities for such experiences may be one of the more important determining causes. This is particularly true for the two thousand five hundred odd Negro physicians practicing in the South, where first class hospitals are not numerous, where contacts with specialists are meager and where educational opportunities have been traditionally limited. In addition, many of these practitioners are the only ones in their communities.

and all too often their net incomes are far below the average for the country as a whole. This study, therefore, is concerned with the extent and development of postgraduate activities designed wholly or in part for Negro physicians in the South.

METHOD

Letters and questionnaires were sent to various organizations located in seventeen Southern states and the District of Columbia. This included twenty-six medical schools, seventeen constituent state medical societies of the American Medical Association, forty-five constituent local and state medical societies of the National Medical Association and twenty-six Negro hospitals fully or provisionally approved. After a number of requests, sixty-nine, or 60 per cent, of the one hundred fourteen organizations returned their questionnaires. The sixty-nine respondents included twenty-five medical schools two of which were the Negro institutions Howard and Meharry, sixteen white state medical organizations, fifteen Negro medical societies and thirteen Negro hospitals. The questionnaires received were analyzed and certain pertinent data about the postgraduate activities in each state for which there is information available have been recorded in the accompanying table. A fuller description of the postgraduate activities in these states will be the subject of a subsequent paper.

ORGANIZATION AND ADMINISTRATION OF PROGRAMS

Only twelve of the seventeen Southern states and the District of Columbia have developed formal postgraduate programs for Negro physicians which are in existence at present and which are held with some degree of regularity. The five states which do not appear to foster regularly such activities are Delaware, Maryland, Mississippi, Oklahoma and West Virginia. Occasionally, however, organizations in some of these states have offered courses. The Maryland State Tuberculosis Association in 1940 cooperated with the District Tuberculosis Association and the Medico-Chirurgical Society of Washington in sponsoring a three day seminar for Negro physicians, and to this came twenty-three Maryland physicians. Such cooperation is being repeated in 1941. In 1936 the Mississippi State Board of Health, with the aid of the U. S. Children's Bureau, offered a two week course in maternal and child care throughout the year, on the circuit plan, for the Negro physicians in the state. Fifty-five of the fifty-eight Negro physicians in Mississippi attended these courses.⁶ In addition, the state health department in cooperation with the Commonwealth Fund sent a Negro physician to Homer G. Phillips Hospital for a ten week course.

There were in the twelve states and the District of Columbia twenty-six opportunities for Negro practicing physicians to engage in continuation study. Of these, nine were sponsored by seven Negro organizations and seventeen by fifteen white groups. Included in the Negro agencies were three hospitals, two medical societies and two medical schools, while the fifteen white groups comprised four medical societies, five medical schools, one board of health and five tuberculosis societies.⁷ Thus it is seen that white organizations, particularly the medical schools and voluntary health agencies, have been more active in this field of endeavor than Negro groups. Of particular significance

is the fact that four Southern state medical societies, namely Arkansas, Florida, Louisiana and Tennessee, have opened certain of their postgraduate facilities to Negro physicians. The attitude of the Florida Medical Association, Inc., is commendatory and deserves a place of prominence. Up to 1940, Negro physicians were not admitted to the one week postgraduate seminar held annually by the society since 1933. In 1940 the last two days of the seminar were opened to Negro physicians and in 1941 the whole course was made available to all duly licensed Negro physicians on the same basis as white physicians. This arrangement has proved satisfactory and should certainly be given a trial by other state medical societies.

Attention must be called to the fact that in only three of the twenty-six opportunities available were the courses of an itinerant nature so that the instruction was taken to the physician in or near his local community. Practically all the courses, therefore, were held in definitely located centers, so that interested physicians had to commute daily or absent themselves from their practice for the duration of the course. This state of affairs compares unfavorably with the situation for white physicians. According to the report of the American Medical Association,⁸ of the one hundred and ten opportunities for postgraduate medical education available in forty-three states, fifty were held in proximity to the physician's home.

SUBJECTS AND INSTRUCTIONS

The subjects offered in these courses may be grouped in five categories. The most common was general subjects of medicine, which was included in eleven of the twenty-six courses. This was followed by obstetrics and gynecology, pediatrics and tuberculosis, which were included either separately or in various combinations in ten, and venereal diseases in eight programs. Next to the general subjects in medicine, the most common combination presented was that of tuberculosis, syphilis, pediatrics and obstetrics. These two types of offerings were the selection in seventeen of the twenty-six courses. It would thus appear that the choice of topics has been based primarily on their importance as disease problems among Negro groups and not particularly on the needs of general practitioners. Nor is there an attempt to organize these courses so that at the end of a certain period of years, let us say four or five, physicians who have regularly attended the courses will feel that they have been educationally refreshed in all sections of their knowledge. In these twenty-six programs, preclinical courses have seldom been included, and such special subjects as malaria, endemic typhus, nutrition and diet, degenerative diseases such as cancer, heart disease and diabetes, which are of importance in the South and in the Negro group, are infrequently touched on.

The instruction in these programs has been through lectures, discussions and clinics. It appears from this analysis that better than half of these offerings have unfortunately depended on lectures and discussions for their teaching procedure. Here again much needs to be done in the organization and presentation of these courses so that they will be most attractive to general practitioners. It has all too often been assumed that men in practice may be taught successfully by the same methods as undergraduates in medicine. This is to be questioned, since even the teaching of medical students is not on too firm a footing.

6. Such a project was also put into operation in 1937 in Georgia and in 1938 in Alabama.

7. These sponsoring agencies, as may be noted in the table, were helped by a variety of other institutions and groups.

8. Council on Medical Education and Hospitals: *Graduate Medical Education in the U. S.*, p. 23.

The duration of the courses varied from three days to a year. The majority of the courses were under one week in length, since ten, or almost half, were in this division. The remainder fell into the following categories: four of one week's duration, six of two weeks, three of one to three months and two throughout the year, and for one no information was given. The two which were offered throughout the year consisted of monthly or biweekly seminars for local physicians.

FINANCIAL SUPPORT AND PHYSICIANS' INTEREST

A variety of organizations have given financial aid and provided personnel and facilities for these meetings. Among these may be mentioned the United States Public Health Service, the United States Children's Bureau, the Julius Rosenwald Fund, the National Tuberculosis Association, the Commonwealth Fund, the General Education Board of New York City and the various local and state official and nonofficial groups. As a result of this, it is found that fourteen, or more than half, of these programs were offered to Negro physicians free of charge. The remaining twelve had extremely moderate registration fees as follows: one of \$1, one of \$3, six of \$5, two of \$10, one of \$15 and one of \$20. From this standpoint, it would appear that Negro physicians have no complaint to offer. The same situation obtains for white physicians where itinerant courses are concerned. Of the fifty courses offered in 1938-1939, thirty-seven charged no registration fee, while the remainder had fees varying from \$2 to \$15. However, for continuation courses featuring clinical material and held at one center, white physicians had to pay larger sums, since in forty-nine of the sixty programs fees varied from \$5 to \$400.⁹

It is difficult to obtain an accurate idea of the total attendance of Negro physicians practicing in the South who participated in these courses in one particular year.

In some of the questionnaires the attendance reported included other professional groups such as those of dentists and nurses, while in others the attendance included physicians practicing in Northern states. The total attendance as reported by these states numbered approximately 1,200 physicians for the year 1939-1940. On the basis of this, it could be assumed that possibly from 800 to 1,000 Negro physicians practicing in the South attended courses offered in that year. This would mean that from 30 to 40 per cent of the Negro physicians in this geographic area availed themselves of these educational opportunities. This percentage compares favorably with the already quoted percentage of 25 for white physicians for the year 1938. Although this comparison is good, it must be admitted that there is a sizable percentage of physicians who are not making any effort to improve themselves continually.

COMMENT

This analysis shows that even though many Southern states have developed postgraduate programs for Negro physicians, the number of these activities is admittedly insufficient; yet facilities and personnel are available in the South which could be developed to the advantage of these practitioners. This applies both to Negro and to white organizations, and certainly the eventual solution of this problem depends on the active and wholehearted cooperation of these two groups. What then are possible approaches to this problem? The following suggestions may be put forth:

1. Negro hospitals, particularly those which have been approved by the American Medical Association and the American College of Surgeons, should develop refresher courses for physicians in their locality. The example of Flint Goodridge Hospital of Dillard University is one worthy of emulation.

2. The medical schools in the South should become more concerned about the postgraduate education of Negro physicians. Of the twenty-five medical schools in this area, only five are at present offering courses for

⁹ Council on Medical Education and Hospitals: Graduate Medical Education in the U. S., p. 42.

Negroes. Certainly it would appear that the other twenty schools would develop programs comparable to those of the Medical College of Virginia, the St. Louis University School of Medicine and Duke University School of Medicine.

3. The examples which have been set by the state medical association of Florida and those of Arkansas, Louisiana and Tennessee should gradually cause other Southern state and county medical societies to open some of their postgraduate activities to Negro physicians. Just as the Florida Medical Association, Inc., gradually opened its postgraduate seminar to Negro physicians in the state, so other associations could experiment in this direction.

4. Negro medical societies also have a responsibility in this sphere which thus far they have neglected. These organizations should develop annual refresher courses of three to five days' duration for their membership. By pooling the resources of their communities, this could be done without too great an outlay of money. The appointment of strong and active postgraduate committees to explore possibilities and formulate plans would be steps in the right direction.

5. The postgraduate programs which are at present in operation should be reevaluated so that the educational needs of the general practitioner are met more fully. Refresher courses would serve a more useful purpose if they were so organized that they would cover definite units of study yearly and bring up to date such basic knowledge as bacteriology, pathology and physiology, in addition to reviewing new technic, methods of treatment and diagnosis in the fields of internal medicine, obstetrics, minor surgery, venereal diseases and the like. Only in this manner will refresher courses have a purposeful meaning.

SUMMARY

1. Twelve of the seventeen Southern states and the District of Columbia have at present postgraduate programs, which are held with some degree of regularity, designed as a whole or in part for Negro physicians.

2. There are in these twelve states and the District of Columbia twenty-six opportunities for Negro physicians to engage in continuation study. Nine of these have been sponsored by seven Negro organizations and seventeen by fifteen white groups.

3. General subjects in medicine are the most popular, since these were offered in eleven of the twenty-six courses. Obstetrics, pediatrics, tuberculosis and syphilis are the other topics most commonly included.

4. The courses vary in length from three days to a year, but almost half are under a week's duration.

5. The majority of the courses are offered free of charge, and those which require a fee have a nominal one varying from \$1 to \$20.

6. Approximately 30 to 40 per cent of the physicians practicing in the South availed themselves of these educational opportunities in 1939-1940.

Industrial Research Laboratories.—Some of the facts relating to the United States are striking. In 1940 two thousand two hundred industrial corporations maintained three thousand five hundred research laboratories which employed seventy thousand workers at a cost of seventy-five million pounds. In these, particular emphasis is directed toward personal qualities of the prospective employee as distinguished from scholarship. Creative urge, receptiveness to new ideas and intellectual integrity are particularly important.—The Spiritual Value of Research, *Nature*, Dec. 6, 1941.

Clinical Notes, Suggestions and New Instruments

A TRANSFUSION REACTION FOLLOWING THE USE OF UNIVERSAL BLOOD

NIELS C. KLENDSHOJ, M.D., AND CRICHTON McNEIL, M.D.
BUFFALO

It is difficult to evaluate the frequency and severity of reactions ascribable to the presence of isoantibodies in universal blood (O blood). Minor reactions may occur frequently while severe and fatal reactions with demonstrable hemolysis or agglutination are relatively rare. The statistical approach to the problem is obviously difficult. However, the literature contains a number of reports some of which state observations only during and following reactions while others include detailed laboratory data necessary for a study of the factors involved. Without attempting to review the literature completely, we shall cite some papers pertaining to the question of the high titered donor.

Levine and Mabee¹ and Freeman and Whitehouse² on the basis of their "in vitro" studies cautioned against the use of "dangerous" universal blood. Wildegans³ discussed the universal donor and referred to several specific accidents. An extensive analysis of reactions to transfusions of group O blood was published in 1935 by Gesse.⁴ This article presents a collection of 46 cases presenting severe hemolytic reactions of which 20 terminated fatally. Muller and Balgairies⁵ reported a transfusion with shock following the administration of universal blood of high anti-A titer to a group A recipient. DeGowin⁶ reviewed his experiences with 3,500 transfusions and commented on one hemolytic reaction in detail in which high agglutinin titers were thought to be responsible. Levine and Katzin,⁷ after corresponding with 350 hospitals, found that 225 used universal donors to some extent and that only 8 used tests to ascertain agglutinin titers. They mentioned three known reactions from this source. MacKay⁸ described a case of acute agranulocytosis in which a transfusion with universal blood was given. The patient afterward became icteric, and erythrophagocytosis was noticed in the blood smear. Schürch and Willenegger⁹ presented fourteen reactions in one hundred and sixty-seven transfusions. Twelve reactions occurred when universal donors were used for A recipients, and 2 of these with well defined hemolytic signs were definitely shown to have high anti-A agglutinin titers. The others were not determined. In an analysis of 3,000 transfusions, Wiener and his co-workers¹⁰ mentioned the dangerous universal donor as a source of reactions.

Through the courtesy of Drs. McKay and Wolfe, we have had the opportunity of studying a hemolytic reaction in a man aged 77 following the transfusion of universal blood.

The patient presented a large, indirect, complete inguinal hernia on the right side which he had attempted to support by means of a truss for the past twelve years. It had always been reducible until two weeks before admission, at which time he complained of pain in the lower part of the abdomen, diarrhea and inability to reduce the hernia. He was hospital-

ized in another institution and the hernia was reduced mechanically, relieving him of his symptoms until five days prior to admission to our hospital. For a period of several months he had been taking digitalis for cardiac irregularity.

On admission the temperature was 99.8 F. rectally, the pulse was 50 and irregular and the respiratory rate was 18. The blood pressure was 140 systolic and 70 diastolic. He complained of severe pain in the lower part of the abdomen without nausea or emesis. On examination, besides the slow irregularity of the cardiac rhythm, the hernia was found to be nonreducible and he was immediately operated on and an incarcerated hernia was relieved and 6 inches of devitalized small intestine was resected followed by entero-anastomosis.

On July 4, 1941, the first postoperative day, signs of ileus developed and duodenal decompression was instituted. The temperature was 103 F. and the blood pressure 150 systolic and 64 diastolic. At 10:30 p. m. a blood transfusion was started. The patient belonged to blood group A, blood type MN, Rh positive. Cross matching was carried out by mixing the cells of the donor and the serum of the patient and keeping the mixtures at room temperature as well as at 37 C. (98.6 F.) for one hour, after which time the tubes were spun down. The cells of the donor were perfectly compatible toward the serum of the patient. A subsequent determination of the titer of the antibodies of the donor's plasma revealed an anti-A titer of 1:128 and an anti-B titer of 1:64 as determined by test tube titration.

The patient experienced a severe chill and a rise in temperature to 106.8 F. after 250 cc. of citrated O blood had been administered. Slight cyanosis was present. The respirations were labored and the pulse weak and thready. The blood pressure was 116 systolic and 68 diastolic.

By 1 o'clock the following morning the blood pressure had fallen to 80 systolic and 40 diastolic and distinct diaphoresis and pulmonary edema were noticed. Treatment consisted of morphine, atropine and oxygen. During the day he responded slightly and the blood pressure returned to 110 systolic and 56 diastolic following the administration of 500 cc. of diluted pooled plasma and 1,000 cc. of 5 per cent dextrose and saline solution. Blood chemistry determinations before the plasma was given revealed dextrose equal to 156 mg. and urea nitrogen equal to 25 mg. per hundred cubic centimeters and sodium chloride equal to 487 mg. per hundred cubic centimeters. The carbon dioxide combining power was 53 volumes per cent. The icteric index of the patient's plasma was found to be 20 with slight hemolysis and biphasic van den Bergh of 0.6 mg. per hundred cubic centimeters. A single specimen of urine was observed to be orange colored with no red blood cells.

The next day therapy with intravenous infusion of saline solution and sodium sulfapyridine was started after definite signs of pulmonary consolidation had been discovered in the left base. The duodenal decompression was continued and the abdomen remained soft.

From July 7 to July 9 the patient was stuporous and incontinent. A blood culture taken on July 6 was reported negative. On July 7 the icteric index was 50 and the van den Bergh biphasic and quantitatively 2.8 mg. per hundred cubic centimeters. The hemoglobin level remained constantly over 100 per cent. The urine looked amber and clear and the sediment showed 7 to 10 red blood cells per high power field. Pulmonary edema became severe and the patient died July 9.

COMMENT AND SUMMARY

About 250 cc. of blood of group O (universal blood) was transfused into a man aged 77 belonging to blood group A. The immediate reaction to the transfusion consisted of a sharp rise in temperature. The increases in the icteric index and the quantitative van den Bergh reaction point to definite hemolysis. The serum of the patient did not influence at all the cells of the donor, as demonstrated by careful cross matching even at 37 C. (98.6 F.). However, the serum of the donor contained a relatively high titer of anti-A antibodies, the presence of which we believe was the cause of the reaction observed. We feel, therefore, that this case demonstrates the fact that O blood containing potent isoantibodies cannot necessarily be considered safe universal blood.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

THE TREATMENT OF VERTIGO AND SYNCOPE

SOMA WEISS, M.D.

BOSTON

This is one of the second series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.

Vertigo and syncope are common symptomatic manifestations, yet many physicians possess inadequate knowledge not only of the treatment but also of the fundamental nature of these states. Although usually vertigo and syncope are unrelated both in their pathogenesis and in their treatment, it is justifiable to consider them together because they are confused with each other. Vertigo, in a strict sense, describes an experience in which the patient has the sensation that the outer world is revolving about him ("objective vertigo") or that he himself is moving in space ("subjective vertigo"). The latter experience can be reproduced simply by subjecting the patient to rapid whirling movements of some duration. Frequently, however, vertigo is used erroneously as a synonym for "dizziness" or "giddiness" to indicate an unpleasant sensation of disturbed relationship to surrounding objects in space. The terms "dizziness" and "giddiness" should be restricted to an abnormal sensation of unsteadiness characterized by a feeling of movement within the head without the experience of the external world or the patient himself being in motion. Dizziness or giddiness, as a subjective sensation, should not be confused with the sensations associated with ataxia. At times true vertigo and dizziness can coexist.

On the basis of such a definition, true vertigo has more specific diagnostic significance in neurologic and psychiatric disturbances than does dizziness or giddiness. Vertigo is usually accompanied by difficulty with locomotion and at times with a sensation of sinking. However, vertigo as a rule has no relation to syncope, while dizziness is frequently a *forme fruste* manifestation of syncope, although dizziness is frequently associated with bodily states independent of syncope. Dizziness is often a manifestation of any one of a number of conditions, which include a minor or severe injury to the head, arterial hypertension, cerebral arteriosclerosis, cerebrovascular accidents, intoxications, petit mal or grand mal epilepsy, cerebral neoplasms or abscesses, epileptic aura, psychoneurosis and psychosis.

Because patients describe vertigo or giddiness indiscriminately as "swimming," "reeling," "dizziness," "light headedness," "faintness," "drunk feeling" or "sense of foolishness" the first step in the treatment of vertigo and dizziness is the proper interpretation of the patient's complaints. Without this, effective treatment is not possible.

Dr. Weiss died, January 31.
From the Medical Clinic of the Peter Bent Brigham Hospital, and the Department of Medicine, Harvard Medical School.

VERTIGO

From a broad physiologic point of view, vertigo is the result of certain types of disturbances of the nervous mechanisms involved in the maintenance of normal body balance. While the "master organs" in maintaining balance are the vestibular portions of the labyrinths with their nerve connections through the vestibular portion of the eighth nerve to the vestibular nuclei in the medulla oblongata, important contributory roles are played by the eyes, the muscles of the head and neck, the deep tendon and the joint sensations in general, and by the cutaneous tactile sensations. It should also be recalled that the vestibular nuclei have intimate anatomic and functional connections with certain parts of the cerebellum and cortex as well as with the centers of the oculomotor, vagus and accessory nerves. Hence certain types of functional or structural disturbance of any of these centers or of their nervous connections can cause vertigo.

Usually in true vertigo external objects seem to move in horizontal planes in rotary fashion. A sensation of vertical movement occurs more rarely. Attacks of true vertigo as a rule develop suddenly, are of relatively short duration and are usually accompanied by disturbed locomotion. The sensation of violent rotation may be so strong that the patient is thrown to the ground. Falling and inability to move without convulsions or without loss of consciousness may be prominent features in severe attacks of vertigo. In some of the attacks of vertigo or Ménière's syndrome, dizziness and vasomotor reactions, and rarely syncope with unconsciousness, can also be present. Frequently nausea and vomiting and usually nystagmus accompany attacks of vertigo. In milder attacks the sensation of rotation may be slight and fleeting. These features, and others, may differentiate the attack from syncope, epileptic seizures and cataplexy. In general the more acute the causative lesion, the more intense the vertigo. Thus a slowly progressing suppurative destruction of the labyrinth is usually not associated with vertigo.

Among systemic diseases, infections, arterial hypertension, severe anemia and leukemia can on rare occasions be responsible for vertigo presumably by causing local hemorrhages or other types of disturbance of the function of the labyrinth or other nervous mechanisms. Arteriosclerosis with thrombosis or rupture of the cerebral vessels can also be responsible for vertigo. Dizziness, however, more often than vertigo, is a symptom of these diseases.

While the most intense type of vertigo is a phase of classic Ménière's syndrome (recurrent attacks of severe vertigo, nausea, vomiting, tinnitus, nystagmus and deafness), vertigo as a presenting symptom is a frequent manifestation of many other organic and transient physiologic disturbances of the brain, including psychoneurosis and psychosis. The present clinical knowledge of vertigo is based mainly on investigations of structural lesions of the seventh nerve and its pathways. The earlier anatomic contributions, however, bearing on the pathogenesis of vertigo and Ménière's syndrome are often not reliable. Thus it is doubtful whether lesions within the bony canal of the eighth nerve are responsible for vertigo, for it would be unusual if such a lesion did not affect the seventh nerve; and yet a combination of vertigo and seventh nerve irritation or palsy is rare in the clinic. In addition to diseases of the labyrinth, among the organic

diseases associated with severe vertigo are concussions of the brain and lesions of the fourth ventricle (brain stem) including those caused by thrombosis of the posterior inferior cerebellar artery, encephalitis and multiple sclerosis. Syphilitic meningitis can cause vertigo if it is associated with a local meningeal reaction in the cerebellopontile angle. Pontile tumors and tumors of the cerebellopontile angle can cause tinnitus and deafness but only rarely vertigo. Cerebellar lesions do not usually cause vertigo, with the exception that tumors of the middle lobe can be associated with vertigo, presumably as a result of secondary irritation of the brain stem. For reasons which are not clear, tumors of the frontal lobe can at times give rise to vertigo.

In by far the majority of instances of severe vertigo alone or in association with tinnitus, vomiting and deafness (Ménière's syndrome), underlying structural lesions cannot be demonstrated. The attacks, which are unpredictable, are usually dominated by vertigo and related symptoms. Interparoxysmally, tinnitus and deafness are the usual features. Frequently in the early attacks vertigo alone or vertigo and tinnitus are the precursors of typical attacks of Ménière's syndrome. The differentiation between Ménière's syndrome and pseudo-Ménière's syndrome is often arbitrary. Muscular unbalance of the eyes can be responsible for vertigo, and caisson workers and aviators may complain of vertigo. Certain drugs such as the salicylates, quinine and nicotine can cause this symptom. Vertigo can be caused at times by respiratory infections such as "grip" or true influenza ("infectious labyrinthitis"), and it may represent an aura in epilepsy or be the equivalent of an epileptic seizure. Disturbance of the cerebral circulation associated with uncomplicated arterial hypertension or with sudden fluctuation of the arterial pressure is usually not responsible for vertigo or Ménière's syndrome. The appearance of attacks of vertigo in patients with arterial hypertension is usually indicative of cerebral vascular accidents.

The point, however, least appreciated by physicians is that in a small group of patients periodic attacks of vertigo or Ménière's syndrome can be the presenting manifestation of psychic disorders. These patients with vertigo of "functional" etiology are often labeled psychoneurotic. They have a nervous system inherited from their ancestors in whom in the direct or indirect line psychoses of varying degree were usually present. Not infrequently, some of the relatives have been "eccentric," "highly nervous," "worrisome" or subject to periodic "nervous breakdowns." The past emotional experiences of these patients are within the normal. Their intellectual endowment and performance are usually normal or above. Periodic interference with normal activity, however, is usually caused by functional disturbance of "vegetative" centers of the brain stem, including vertigo. Some of these functional disturbances follow strict physiologic patterns, and the severity and periodicity of the clinical picture varies considerably. These persons may have a low basal metabolic rate without myxedema. Periodic nystagmus, transient hyperactivity of the carotid sinus reflexes, excessive vasomotor fluctuations including vasospasms, disturbances of the thermal sensations and regulations, nausea, vomiting, intestinal cramp, allergic reactions and mucous colitis are present in various combinations. Associated with these disturbances are attacks of emotional anxiety (angor animi) and a sensation of bodily weakness. The symptoms of these patients, including vertigo, may have

a tendency to recurrence without progression. At times, however, these attacks long precede a psychosis. It is essential that this group of patients should not be confused with patients suffering from vertigo with secondary anxiety neurosis.

From the foregoing considerations of the underlying disturbances, it is clear that an effective schematic treatment for vertigo cannot be expected. Whenever feasible the primary cause of vertigo should be rectified. It is for this reason that elicitation of the specific cause of vertigo is the first step in its treatment. Elimination of foci of infection, including removal of teeth, tonsils and gallbladder, often advocated, are usually useless or at best of only secondary importance. Rest in bed during the attacks with avoidance of bodily motion ameliorates the intensity of vertigo. We do not possess drugs with a specific effect on vertigo. In mild cases chloretone or chloral hydrate or bromides 0.75 to 1 Gm. (10 to 15 grains) every four to six hours can be helpful. The barbiturates, especially phenobarbital, are usually but mildly effective. Of phenobarbital or pentobarbital 0.1 Gm. (1½ grains) is given three to four times daily. There are patients with vertigo or Ménière's syndrome in whom the symptoms are aggravated by barbiturates.

The treatment of vertigo associated with Ménière's syndrome requires special consideration. The very fact that a beneficial effect has been attributed to so wide a variety of therapeutic agents raises suspicion concerning their true efficacy. Epinephrine, atropine, quinine, choline derivatives, pilocarpine, histamine, dehydration, low sodium-high potassium diets, potassium chloride, nicotinic acid, thiamine, the high frequency current and diathermy are among the measures advocated. Therapeutic optimism, lack of adequate controls, irregular occurrence of the attacks and, most of all, lack of appreciation of the fact that many instances of Ménière's syndrome are transient and often of functional origin explain the short life of these various therapeutic claims. Many of the patients with vertigo or with Ménière's syndrome are quite susceptible to psychotherapeutic influences. Often minute attention to the patient and general encouragement rather than the drugs are the effective component in the management.

Among the more recent therapeutic practices the following should be mentioned: Mygind and Dederding¹ were the first to advocate that Ménière's "disease" is associated with disturbance of the salt and water metabolism and that edema of the labyrinth is responsible for the symptoms. Furstenberg, Lashmet and Lathrop² claim that retention of sodium and resultant local edema intensify or are responsible for the attack. They propose a dietary regimen free from or relatively low in sodium in which elimination of sodium is enhanced by the addition of ammonium chloride. Ammonium chloride is given in doses of 3 Gm. (6 enteric coated capsules each 0.48 Gm.) three times daily with meals, added to the diet. Talbott and Brown,³

however, were unable to demonstrate chemical changes indicative of sodium or water retention in the blood, and they concluded that gross retention of water and salt by the body is not the precipitating agent in acute attacks. These authors suspected that in the low sodium diet the relative and often absolute increase in the potassium content was the effective agent. They therefore undertook a study of the effect of a diet normal in sodium to which 6 to 10 Gm. of potassium chloride had been added daily. These investigators claim that, although such a therapeutic regimen cannot be considered as a cure for all the symptoms, nevertheless clinical improvement has been impressive. None of the 48 patients required surgical treatment. The precise action of potassium chloride in vertigo, however, remains unknown. Talbott and Brown suggest that in addition to the diuretic effect of potassium chloride, which hastens the elimination of water and sodium, a disturbance of the optimal concentration of potassium interferes with normal nerve conduction.

In the majority of cases the dietary and drug regimens outlined had to be maintained indefinitely. Both the original and the modified low sodium dietary regimens lack, however, definite rational biochemical and physiologic basis. Although several reports in the literature describe improvement or relief as a result of the low sodium or high potassium methods of treatment, this therapy failed to benefit appreciably the attacks of vertigo in a group of patients that I observed during the past seven years. Further, the specificity of the low sodium or high potassium regimen is rivaled by similar claims of benefit from several other methods of treatment.

Sheldon and Horton⁴ claim that the intravenous administration of histamine is beneficial in the attacks of Ménière's disease. About 1.9 mg. of histamine phosphate in 250 cc. of physiologic solution of sodium chloride was infused during a period of one and a half hours. This infusion was repeated on two or three successive days with some of the patients. No other medication was used simultaneously for 11 patients, and 8 others received ammonium chloride and potassium nitrate for several months. A strikingly beneficial effect is attributed to histamine in Ménière's disease by these investigators. From what is known of the bodily effects of histamine and of its short persistence of action, it is difficult to understand the rationale of this procedure. Until further confirmation of this work, no final opinion can be expressed on the therapeutic value of histamine in the treatment of this type of vertigo. Horton⁵ has stated recently that about 90 per cent of the patients treated with histamine administered intravenously experience recurrent attacks of vertigo unless there is continued treatment with histamine subcutaneously or with one of the other forms of medical procedure.

Harris and Moore⁶ claim beneficial results in the treatment of Ménière's syndrome with a diet high in vitamins and proteins. To this diet nicotinic acid and thiamine are added. Atkinson⁷ suggests, on rather

meager evidence, that Ménière's syndrome is the result of vasomotor disturbance, which in one group of cases is allergic in origin and in the other is due to vasomotor spasm. According to Atkinson the allergic group can be benefited by intracutaneous and subcutaneous desensitization with histamine. In the vasoconstrictor group it is claimed that nicotinic acid and thiamine are beneficial.

Just as the medical treatment of vertigo has failed to yield clearcut results, so also have certain types of surgical therapy. For about a decade "surgical decom-

pression" of the labyrinth has been practiced, particularly by the British surgeons. This practice has been based mainly on the suggestions of Cheatle,⁸ who claimed that Ménière's syndrome depended on increased pressure in the labyrinth. Notwithstanding the claims for their effectiveness, these procedures are no longer practiced. At present intracranial division of the auditory nerves is performed in the treatment of severe recurrent vertigo of Ménière's syndrome. Although Charcot as early as 1874 suggested this operation and Frazier⁹ performed it in 1912, it was Dandy¹⁰ who first prac-

ticed it effectively, doing a partial or complete resection. Benefit from this surgical procedure has been reported by others.¹¹ Crowe¹² more recently reported the therapeutic results with a group of 94 patients operated on by Dandy. In 49 cases the auditory nerve was divided completely and in 45 cases only partially. Vertigo was relieved in the entire group, while the improvement in the tinnitus was less uniform, in some instances being worse after the operation. In the group with partial resection the hearing improved in 22 per cent, but in others it became worse. If this surgical procedure is advised, the patient should clearly understand that tinnitus will probably persist.

Destruction of the labyrinth and the ganglion of Scarpa, either through the middle ear¹³ or through the roof of the petrous bone,¹⁴ has been practiced with apparent benefit. Walsh and Adson¹⁵ in comparing medical and surgical treatments observed improvement in three groups of patients treated respectively with low sodium diet alone, low sodium diet with ammonium chloride, and low sodium diet with potassium nitrate. They believe that section of the vestibular portion of the eighth nerve is the most effective surgical measure. Such an operation, however, should be advised only after prolonged medical treatment and only if the patient's vocation precludes attacks of vertigo, or if his economic status does not allow loss of time from labor for hospital care or prolonged medical treatment.

The present status of the treatment of vertigo in Ménière's syndrome may be summarized as follows: Patients suffering from vertigo or from Ménière's syndrome should first be managed medically. In every case a thorough search should be made for the primary underlying organic or physiologic mechanisms. These primary mechanisms should be eliminated or alleviated if possible. Fatigue, infection and physiologic and psychic stress should be avoided. Psychotherapeutic encouragement is often effective. Sedation and bed rest during the attacks are indicated. Low sodium diet or a normal diet with potassium chloride may be tried, but the value of these methods of treatment has not yet been established. If after one or preferably two years of carefully conducted medical treatment improvement does not occur, and if the attacks are severe and frequent, surgical treatment may be considered. Surgical intervention, however, is indicated in but a small, selected group.

SYNCOPE

Syncope is a syndrome dependent as a rule on a rather sudden and usually transient ischemic state of the arterial system. Syncope or related states are caused, at times, by vascular reflexes affecting certain cerebral functions. This is the case in the cerebral type

TABLE 1.—Comparative Features of Syncope and of Epileptic Seizures

	In Syncope	In Epilepsy
Predisposing factors		
Emotion.....	Frequent	Fairly frequent

of carotid sinus syncope. Syncope is one type of the shock syndrome.¹⁶ The clinical manifestations of syncope are primarily those of acute cerebral ischemia and anoxia (anoxic syndrome). In the classic instance of syncope there is unconsciousness, at times associated with mild clonic convulsions. In elderly persons convulsions may be a prominent feature in an attack of syncope. If, however, the ischemic state of the central nervous system is mild, light headedness, weakness, dizziness, scintillating scotomas, dimness of vision, "black out," unsteadiness or nausea and vomiting may be the *forme fruste* manifestations. These symptoms may be absent if the underlying physiologic mechanism is set in action with great rapidity. A sensation of rotation, characteristic of vertigo, is usually absent in syncope.

Some persons experience auras that are similar to those occurring before the onset of epileptic fits. As a rule the duration of syncope or syncopal equivalents is less than that of vertigo. In vertigo the duration of the attack is usually measured in hours; in syncope it is measured in minutes. Syncope is dependent primarily on a disturbance of the circulation; vertigo, as already indicated, depends on the disturbance of specific nerve structures and functions.

In most types of syncope the derangement of the circulating blood volume takes place within the cardiovascular system. In a small group of patients, however, hemorrhage is responsible for syncope. Usually either the heart suddenly fails to take care of the inflow of blood (cardiac syncope or acute cardiac shock) or the venous blood flow is rapidly diminished as a result of active or passive dilatation of portions of the vascular bed (vascular syncope). In the shunting or pooling of blood the venous system frequently plays an important role.¹⁷ Among the common causes of syncope are (a) nervous conditions (psychogenic factors, pain or other reflexes, structural lesions of the central nervous system), (b) gravity, (c) chemical factors including anoxia, (d) hemorrhage.¹⁸ Although recovery from syncope is the usual course, syncope can be fatal. Because of the importance of gravity in the pooling of blood within the vascular system, to allow the body to remain in an upright or a sitting position during syncope is particularly dangerous. All types of syncope are more prone to occur in the upright, immobile position, and syncopes developing when the body is in a horizontal position are usually of graver significance. For example, in patients with bleeding peptic ulcer, syncope which develops while the patient is resting in bed is indicative of serious internal hemorrhage. In the presence of increased irritability of the cardiac reflexes and of the myocardium such as develops in association with coronary sclerosis, thrombosis or aortic stenosis, and after certain infections such as influenza, streptococcal infections or rheumatic fever; fatal syncope due to asystole or to cardiac irregularities such as ventricular fibrillation or to vagal inhibition with asystole is prone to occur.¹⁹ Whenever death occurs

unexpectedly and truly instantaneously, the most probable cause for it is syncope and not acute organic diseases such as cerebrovascular accidents or pulmonary embolism. The onset of pulmonary embolism or fresh coronary infarction can at times be associated with instantaneous death, but it is probable that in these cases the superimposed reflex inhibition of the heart is the immediate cause of death. In the presence of severe organic diseases of the cardiovascular system the same type of syncope is, as a rule, of graver prognostic significance than in normal persons. Whereas in normal persons, owing to the presence of numerous emergency functions and the reserve capacity of the vital organs, a return to normal equilibrium is accomplished with relative ease and promptness; in diseased or aged persons, because organs are damaged and homeostatic capacity limited, a return to the normal level becomes more difficult, is slower and may not occur.

There is an intimate relationship between the fundamental underlying physiologic mechanisms of syncope,

TABLE 2—Types of Syncope in Morbid States

Condition	Type of Syncope
Neurosis, nervous strain	Vasovagal
Mountain sickness.	Vasovagal

General anesthesia	Carotid sinus, vagovagal
Local anesthesia	Central type

collapse and shock. This close relationship is indicated not only by the similarity of the fundamental mechanisms but also by the fact that the same noxious influence, depending on its intensity and duration, can produce syncope, collapse or shock. Thus gastric hemorrhage can be responsible for any of these three syndromes. For the most part the intensity of the stimulus, the time element, the ease of reversibility and the secondary changes in the vessels and tissues are the chief differential features between syncope, collapse and shock.²⁰ Syncope should be carefully differentiated from attacks of epilepsy, Ménière's syndrome and cataplexy. The differential characteristics of syncope, vertigo and Ménière's syndrome have already been described. The important criteria for the sometimes difficult differential diagnosis to be made between faints (syncopes) and fits (epileptic attacks) are summarized in table 1.

A classification of the various types of syncope and the details of differentiation have been discussed elsewhere.²⁰

In addition to these general considerations, a knowledge of the physiologic mechanisms underlying the

various types of syncope is essential in the treatment. Table 2 lists the more common types of conditions associated with syncope and the specific types of syncope usually associated with the conditions.

Different types of syncope may require diametrically opposite treatment. Certain general therapeutic principles, however, should always be remembered. In general in most types of syncope, particularly the vasovagal type, in which often psychogenic factors and the upright position play important roles, the attack will usually cease after the body is brought into the horizontal position and the lower extremities are elevated. Persons with a tendency to vasovagal syncope, when standing motionless, should be instructed to maintain rhythmic isometric muscular contractions. Although in the majority of instances of vasovagal syncope vagocardiac inhibitions play some role, experimental evidence indicates that parenteral administration of atropine in doses of 2 to 6 mg.—a dose large enough to depress the vagal influence—does not usually prevent the attacks. Vasovagal syncope can occur, particularly in the upright position, after the administration of vasodilator drugs, such as the nitrites and choline derivatives. To prevent these attacks it is essential to keep the patient in the horizontal position after the administration of the drug. Persons with severe aeroplagnia can suffer from vasovagal or vagovagal types of syncope caused by the combination of the distention of cardia and esophagus and the psychic factors present. Reeducation of these patients may cure the attacks.

Syncope is prone to occur in the course of infectious diseases if the upright position is assumed. This type of syncope is usually vasovagal in character, and increased distensibility of the minute vessels plays a role. Heightened sensitivity of the heart to vagal inhibition can also be a factor. It is of interest that often the tendency to syncope is greater with a mild upper respiratory infection than after prolonged bed rest of weeks' or months' duration.²¹ This is of practical importance particularly in aviation medicine. Aviators should not be allowed to fly at a high altitude when suffering from even a mild respiratory infection.

In attacks of syncope in which vagal inhibition is the primary factor (the cardiac type of carotid sinus syncope and the vagovagal type) doses of atropine (1 to 3 mg.) or tincture of belladonna (1 to 3 cc.) may prevent the occurrence of the attacks. At times, however, toxic side reactions to these drugs interfere with the therapeutic efficacy of these drugs. Epinephrine in hypodermic doses of 0.5 to 1 mg. is effective in the relief or prevention of the vasovagal, the vagovagal, the cardiac or the vascular types of carotid sinus syncope and Adams-Stokes attacks caused by complete dissociation of auricles and ventricles. Digitalis at times enhances the tendency to syncope in patients with heart disease. In some patients with normal sinus rhythm with tendency to Adams-Stokes attacks, ephedrine in oral doses of 30 to 40 mg. every four to six hours may prevent attacks. It has been shown that the efficacy of ephedrine in these patients does not necessarily lie in its ability to prevent the occurrence of the block but rather in its tendency to induce increased irritability of the myocardium. As a result of this hyperirritability when the block occurs an effective idioventricular

rhythm develops instantaneously.²² Barium chloride has been found in my experience to be ineffective in the prevention of Adams-Stokes attacks due to heart block.

Syncope or equivalent manifestations caused by paroxysmal tachycardias are treated according to the underlying intracardiac disturbances. In the treatment of dizziness or syncope caused by paroxysmal auricular tachycardia the effective measures are usually those which induce prolonged vagal stimulation.²³ Among the simplest of these are pressure on the carotid sinus or on the eyeballs, bending with the head down, rapid swallowing, holding the breath, distention of the stomach with gas liberated from the ingestion of compound effervescent powders, self-induced vomiting, and stretching of the rectal sphincters. Administration of 10 to 20 mg. of morphine or 3 to 5 mg. of apomorphine can be effective. Digitalization, using up to 1 or 1.5 Gm. total dose of the U. S. P. powder, may be indicated. In my experience syrup of ipecac in doses of 4 to 12 cc. is often effective even in obstinate cases. In the prevention of the attack quinine or quinidine in the usual therapeutic doses (0.2 to 0.4 Gm. every four hours) may be effective. Auricular flutter is only rarely responsible for syncope. In these rare instances effective doses of digitalis should be administered. If, following the appearance of auricular fibrillation, spontaneous sinus rhythm does not develop, administration of quinidine in doses of 0.2 to 0.4 Gm. every four hours is indicated. Ventricular tachycardia can be responsible for syncope or equivalent cerebral symptoms, and administration of quinidine or quinine is the measure of choice. In severe or resistant cases intravenous therapy is justified, although the method of treatment is not without danger. Doses of 0.3 to 0.5 Gm. should be administered in 20 cc. solution slowly in the course of fifteen to twenty minutes. Cough, asthma, cyanosis or accentuation of symptoms is an indication for interruption or discontinuation of this therapy. I have seen attacks of ventricular tachycardia lasting for days, which were resistant to various types of treatment until a dose of quinidine sulfate as high as 1 Gm. was given intravenously. In some instances of ventricular tachycardia magnesium sulfate administered intravenously is apparently effective. In a case observed recently, an attack lasted two to three hours and ceased within five minutes after the slow intravenous administration of 3 Gm. of magnesium sulfate in a 50 per cent solution. For the prevention of ventricular tachycardia and ventricular fibrillation caused by coronary thrombosis, routine quinidine therapy has been advocated. It is difficult to evaluate the efficacy of this treatment.

Syncope associated with pleural or pericardial shock often can be prevented by performing surgical manipulation (taps) in the horizontal rather than in the sitting position, by using local anesthesia and by administering atropine before the manipulations. Inflamed surfaces of the pleura are particularly prone to increase the pleural reflexes.

The treatment of syncope caused by orthostatic hypotension is not very satisfactory. It has been shown recently that often this is a manifestation of disease

22. Weiss, Soma, and Ferris, E. B., Jr.: Adams-Stokes Syndrome with Transient Complete Heart Block of Vagocardiac Reflex Origin: Mechanism and Treatment, *Arch. Int. Med.* 54: 931 (Dec.) 1934.

of the sympathetic nervous system in which hydrostatic pressure plays an important role.²⁴ In patients with syphilitic diseases of the nervous system, particularly dementia paralytica and tabes, syncope is caused by orthostatic hypotension. Some of these patients have an increased tendency to syncope and collapse during fever therapy. The morning dizziness or syncope of the aged may be caused by a tendency to orthostatic hypotension at that time of day. This and other types of orthostatic hypotension may improve as the day goes on. In the less severe cases, such as occur in the aged, mild morning exercise and a cup of tea in bed one half to one hour before getting up may be effective. Ephedrine sulfate in doses of 25 to 50 mg. or paredrinol (*α*-N-dimethyl-p-hydroxyphenethylamine) and presumably parcdrine in doses of 10 to 20 mg. intramuscularly are also helpful. In addition to these measures, bandaging of the extremities and abdominal binders may help.

The treatment of syncope associated with toxic reactions caused by local anesthetics consists of treatment of the poisoning caused by the drug. In the prevention of these toxic reactions administration of barbiturates in doses of 0.2 Gm. of phenobarbital, pentobarbital or amytal is effective. Syncope associated with hemorrhage or severe anemia should be treated specifically with transfusions of blood or proper blood substitutes (plasma or albumin solutions), or with specific measures for the treatment of chronic anemias (iron and liver extracts). Hypoglycemic reactions can be responsible at times for syncope. In these cases administration of dextrose, avoidance of overdoses of insulin or surgical removal of the adenoma of the islands of Langerhans or of other neoplasms of the glands of internal secretion are the effective therapeutic measures. There are patients suffering from angina pectoris who, with some or all of their attacks of angina, develop syncope (syncope anginosa) or milder manifestation. The drugs effective in the prevention of angina will also prevent the fainting or cerebral ischemia. If the patient is receiving digitalis, this should be discontinued. Rarely patients with advanced ("fishmouth") mitral stenosis or congenital heart disease suffer from syncope or milder equivalent symptoms on exertion. As this type of syncope depends on inadequate cardiac output caused by mechanical impediment, avoidance of physical stress is the only preventive measure available. The syncope associated with aortic stenosis is usually associated with bradycardia, but the exact nature of this type of syncope is not known at present. In instances of carotid sinus syncope, particularly in the cerebral type, which do not yield to simple measures which prevent mechanical stimulation of the sinus or to specific medication, surgical denervation of the sinus is indicated.²⁵ Rarely surgical removal of irritating structures which are responsible for reflex syncope may cure the patient.²²

Thus it will be seen that the treatment of syncope depends on the underlying etiology and physiologic mechanism. In each case effective therapy can be undertaken only after the pathogenic factors have been elicited.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

SIMPLE WORKABLE RESPIRATOR

An epidemic of poliomyelitis of major proportions struck the Northern peninsula of Michigan in the fall of 1940. Within a period of a few days 90 patients were rushed by train, by automobile and even by airplane into St. Luke's Hospital at Marquette, Mich. The respiratory type of paralysis was unusually prevalent among the affected children. Only one respirator was available, and at least 12 children needed assistance.

The superintendent of St. Luke's Hospital appealed to Mr. M. K. Reynolds, one of the trustees, for help, insisting that with his engineering ability he surely could devise some type of temporary respirators that could meet the problem until regular respirators could be obtained. The machine shop which Mr. Reynolds maintained at his private boat yard immediately was turned into a respirator laboratory. Cabinet makers and machinists were called in and within a few hours crude but workable respirators were delivered to the hospital. Their first homemade respirator consisted of two gasoline drums welded together and fitted with a hand manipulated valve; this apparatus was attached by a hose to the one available large respirator as a "trailer." Two children were placed in this "trailer," and women of the community worked the valve by hand constantly for thirty-six hours, or until a mechanical automatic valve was constructed. The thrilling story of this volunteer community effort to meet the respiratory problem when commercial respirators were not available was published in the December 1940 issue of *Hygeia*.

Since that article was published, Mr. Reynolds has received numerous letters and many personal visits from representatives of remote communities where poliomyelitis has broken out and where the respiratory problem has become as acute as it was in Marquette. For example, an epidemic has been raging in Alaska. Respirators were needed. An appeal came to Mr. Reynolds and he sent photographs and working plans for making this simple wooden respirator which had proved so valuable in the Marquette epidemic. In his opinion these respirators could be made within a few hours in any school manual training shop, should the emergency arise.

That there is a great need for emergency respirators was recognized by Drs. Phillip Drinker and Edgar Roy, who published specifications for making such an apparatus in the *Journal of Pediatrics* (13:71 [July] 1938). This need is also evident from the urgent requests which have come to the office of the Council during the past year from various parts of the country asking for information as to the location of available respirators. The National Foundation for Infantile Paralysis on July 1, 1941 published a complete list of respirators, giving locations and owners, which may be obtained from the foundation at 120 Broadway, New York City.

It has long been recognized that the need for respirators arises in time of great emergency and that commercial respirators are not always available when needed. Furthermore, a simple respirator such as this should prove useful for intermittent home use to a limited number of badly paralyzed patients who have been hospitalized for many months. Since the respirator can be built cheaply, it can meet an economic problem heretofore almost unsurmountable for patients who require prolonged assistance of a respirator.

Mr. M. K. Reynolds has given to the Council on Physical Therapy a complete set of drawings with instructions for building this simple workable respirator. A pamphlet which graphically sets forth its construction has been prepared and is available for distribution on application to the Council on Physical Therapy of the American Medical Association. This pamphlet should enable any community far removed from a supply of commercial respirators to build this life saving device.

The Council on Physical Therapy has reviewed the plans for making this simple wooden respirator and has authorized the publication of this pamphlet. We feel that Mr. Reynold's gift to humanity merits the gratitude of the entire profession.

DOCTORS' DOLLARS FOR BONDS

Since "Jap Sunday" this nation has been resolute for total victory. In this war physicians will play multiple roles. Through the Procurement and Assignment Service every physician will have opportunity to contribute services to the armed forces or to the care of civilians. Most physicians who serve the armed forces do so at a considerable financial sacrifice. Physicians who remain at home may also contribute by lending money to the government to pay for the tools of war.

To the largest possible extent it is the announced policy of our government today to pay as we go. This means that each year as much as possible of the annual cost of the war effort will be paid out of taxes. The President has asked that funds from the various taxes be increased during the next year by \$9,000,000,000. But the tax total will not be sufficient to meet the cost of the war effort. To obtain the money to push the war effort to the maximum, the Treasury has asked every earner to lend dollars to the government through the defense savings program. The purchase of a bond makes the buyer an active helper in the country's effort. Moreover, money put into defense bonds helps to curb inflation.

As an accepted leader in the community the physician may do much to aid the sale of defense bonds. Each person who buys a bond or a stamp regularly builds himself a personal financial reserve just as good as cash in the bank. Such reserves will help take care of any emergency need, in health or in illness, and will serve as security for the distant future. This is the American way; the individual assumes in large measure responsibility for himself.

There are three series of defense savings bonds, known as E, F and G. Each is designed to meet a different sort of buyer, with a different kind of need.

Series E bonds are the "people's bonds." They may be bought only by individuals in their own rights and are cut to fit all sizes of pocketbooks with a limit on holdings of \$5,000 maturity value of bonds issued in one calendar year. The people's bonds are appreciation bonds which cost 75 per cent of their face value, and the government pays back the full amount at the end of ten years. The $33\frac{1}{3}$ per cent increase is equivalent to an annual return of 2.9 per cent compounded semiannually. They may be registered in the names of one or two persons or in the name of one person with a second listed as beneficiary. To protect the buyer of a bond, it is made so that he cannot sell it or use it as security for a loan, but he may redeem it any time after sixty days from the date of issue. The smallest of the people's bonds costs \$18.75. But this is not the smallest amount that can be put into defense savings. Smaller amounts of money purchase savings stamps, which can be bought for as little as 10 cents. Money invested in stamps does not bring interest, but \$18.75 in stamps can be turned in for one of the registered interest bearing bonds. Nearly every post office in the nation has a bond and stamp window. Nearly every national and state bank in the United States has bonds for sale. Tens of thousands of retail stores have stamps.

The F and G bonds are largely for associations, corporations and other large investors. Formerly the smallest series F bond cost \$74, but the demand from organizations for a smaller denomination bond has been so great that now the Treasury is offering a \$25 series F bond which costs \$18.75. The bonds of series F are purchased for 74 per cent of their face value and at the end of the twelve year maturity period provide a return equivalent to an annual interest rate of 2.53 per cent compounded semiannually. F and G bonds are redeemable by the owner on one month's notice after six months of the issue date of the bond. The owner is limited to \$50,000 (cost price) of series F bonds alone or in combination with series G bonds originally issued to such owner in any one calendar year.

Series G bonds are intended for those who wish to receive a current income from their investment. Their cost is the same as their face value, and they are issued in denominations from \$100 to \$10,000. These bonds mature twelve years from the date of issue, and interest is payable semiannually at the rate of 2.5 per cent if carried through to maturity.

Although bonds of series F and G are issued only by Federal Reserve banks and the Treasury Department, commercial banks generally will handle applications for them.

The physicians of America have never refused responsibilities placed on them in time of war. They are responding now to every demand. They may be counted on to do their full share in the defense savings program.

HOW TO RELAX

"If we could learn how to balance rest against effort, calmness against strain, quiet against turmoil," says Dr. Josephine Rathbone, "we would assure ourselves of joy in living and psychophysical health for life." The psychologists believe that people who live dynamically without being too tense have four main attributes: first, rhythm, in their activities with great swings in output and accomplishment, alternating with periods of repose; second, a sense of values which makes it possible to minimize effort and minimize strain; third, ability to reduce muscular tension in any part of the body consciously whenever desired, and, fourth, a readiness to fall asleep at will.

While these attributes may develop spontaneously to some extent in some persons, it is also possible to cultivate them in a measure. In order to aid such cultivation, ten tricks are presented which are believed to be useful in realizing relaxation. They are:

1. Cut down on the intensity of your thinking half an hour before retiring. (Play Chinese checkers, plan an excursion for the week end, write a letter to a friend, fill with pleasant things you have been doing.)

2. Take plenty of time to get ready for bed (next morning's clothes, leisurely bath, and so on).

3. If you like to read in bed choose nonfiction or a "hard" book. Force your mind to grapple with cumbersome facts, bore it into unconditional surrender to sleep.

4. Transplant your mind from fears or hates to a field which has interest without excitement (a new wardrobe, possibly).

5. Make your mind hop from one idea to another. Just as the mind loses consciousness and sleep comes, thoughts become disjointed and scattered. (Start with some happy episode in childhood, for example.)

6. To quiet the body, get rid of any pressure or pain. (Lighten weight of covers, clothes.)

7. Tepid bath without a rubdown. (Get into bed a little damp and chilly. As the body becomes warmed it becomes more and more comfortable. If during the night one becomes sleepless, throw back covers until body becomes uncomfortably chilly. Then when the covers are pulled up again, the body once more sinks into coziness.)

8. Imitate the slow, deep rhythmical breathing of sleep. (Helps regulate the circulation and may ease the mind and emotions; also tensions in the abdomen.)

9. Relax the muscles completely.

10. Get rested before trying to sleep. (Get into bed an hour or more before your regular time for retiring. Do so night after night to build up a reserve of rest and fall asleep without the old struggle.)

The balance between what can be accomplished by education and practice and what is innate in producing

relaxation and longevity is a delicate one. Physicians have long known that people with a low blood pressure, a low basal metabolic rate, a low pulse rate and a low intake of food—if all of these are not too low—tend to live longer than those in whom these physical factors are at extremely high levels. Perhaps equally important is a low threshold for the sense of humor—a mental attitude which does not take life too seriously.

NEW AIDS IN THE DIAGNOSIS OF LYMPHOGRANULOMA VENEREUM

The possibility of widespread latent infection with lymphogranuloma venereum in this and other countries has been recognized since the Frei test came into more general use. Many persons under observation for other venereal diseases repeatedly have been found with a positive test for this disease. Frei¹ refers to nine papers published before 1936, all mentioning the existence of latent lymphogranuloma venereum in normal persons and in prostitutes. In all those studied the latent infection was indicated by positive Frei tests. Singularly, in many of the so-called normal persons with a positive test a record of infection with lymphogranuloma venereum was lacking. Clinical evidence also is available indicating that other obscure conditions, particularly of the lower bowel, may be related to lymphogranuloma venereum; this fact is emphasized by the paper of Palmer, Kirsner and Rodaniche in this issue of *THE JOURNAL*, page 517.

During the past year the Squibb Institute for Medical Research, collaborating with workers² from Long Island College of Medicine, has developed methods which offer promise for a more refined study of lymphogranuloma venereum. The Frei antigen, as first described, consisted of sterile pus from an unruptured bubo in a person without history or evidence of other venereal disease. The original antigen has disadvantages. There were few cases free from evidence of other venereal diseases which have buboes without secondary bacterial infection; even then the amount of pus in such buboes is small and its potency varies with the individual. Numerous unsuccessful studies have been made to discover other sources of Frei antigen. These investigators and their associates have demonstrated that the virus of lymphogranuloma venereum can be propagated in large amounts when inoculated into the yolk sac of the developing chick embryo. The virus thus propagated can be separated readily from much of the yolk and tissue components by differ-

1. Frei, Wilhelm: On the Skin Test in Lymphogranuloma Inguinale: A Brief Review and a Discussion of Some Possible Causes of Error, *J. Invest. Dermat.* 1: 367 (Oct.) 1938.

2. Rake, Geoffrey, and others: New Aids in the Diagnosis of Lymphogranuloma Venereum, *Am. J. Syph., Gonorr. & Ven. Dis.* 25: 687 (Nov.) 1941.

ential centrifugation. This discovery has not only made possible the production of a large amount of the virus of lymphogranuloma venereum for experimental and clinical use but has led to the hope that an antigen could be produced for a successful complement fixation test for diagnostic use.

The new yolk sac antigen is prepared by liberation of the virus from the cells of the yolk sacs by grinding with abrasion, and suspending the material in saline solution; by separation of the virus from the yolk sac constituents by differential centrifugation and dilution of the final virus-containing sediment in saline solution to a volume two hundred or more times that of the original yolk sacs, and then by inactivating the virus by addition of solution of formaldehyde and phenol to final concentrations of 0.1 per cent and 0.25 per cent, respectively; sterility tests are then made in suitable culture mediums and in the yolk sacs of normal eggs. This antigen has been used successfully in the intradermal Frei test carried out in the usual way with 0.1 cc. of the antigen and read forty-eight or seventy-two hours after inoculation. These observers found that the antigen can be employed satisfactorily in the Frei intradermal test, that it was more sensitive than mouse brain antigen and that it has little power to sensitize patients to the antigen or to egg products. Most of the many investigators who have tried to develop a complement fixation test for lymphogranuloma venereum have failed to demonstrate a specific reaction. The present investigators and their collaborators,² using the yolk sac antigen, have successfully demonstrated complement fixing properties in the serum of infected patients. The complement fixation test as used by them was notable for simplicity and rapidity of performance. Although overnight fixation in the refrigerator results in slightly higher titers for "positive" serums, this time consuming refinement is not necessary. A specimen of serum submitted for the Wassermann test can be employed equally well in the test for lymphogranuloma venereum. There is no necessity for the patient to return a second time as is the case in the reading of the Frei test. Extensive observations made during this study in a case of accidental laboratory infection suggest that complement fixing properties may appear in the serum within a week after the onset of symptoms. In this case the Frei test became negative after chemotherapy, while the serum still showed specific complement fixation. In fact all the indications obtained by these workers were to the effect that the test is more delicate than the Frei test in detecting borderline cases. The test may prove useful in epidemiologic surveys to determine the incidence of lymphogranuloma venereum among the general population.

Current Comment

DOCTORS FOR BRITAIN

With the entrance of the United States into World War II, our project to aid Great Britain by supplying medical volunteers for the British emergency medical service and also for the British army came to an end. It is understood that American physicians in Britain will be given the opportunity to join the American forces. Among the physicians sent to Britain were twelve women who, it is understood, will continue their work in Great Britain. The total number of physicians sent to Great Britain in this project was well under one hundred. The American Red Cross and the British Red Cross have expressed appreciation of the efforts of the medical profession to aid them in securing such medical personnel as they were able to secure in this way.

EMERGENCY RESPIRATOR

When an epidemic of poliomyelitis strikes suddenly, medical and hospital facilities are sometimes inadequate to cope with the situation. Especially is this true when extra respirators are urgently needed. Hospital authorities who wish to serve their communities efficiently are nevertheless confronted with the perplexing decision as to whether or not an investment supplies facilities whose use justifies their cost. Some hospitals cannot afford to purchase a commercial respirator; other institutions may have one or possibly two respirators lying idle in the store room most of the time. Often during epidemics ten times the available local supply of respirators may be demanded. The National Foundation for Infantile Paralysis has published a list of respirators giving the location of owners; the headquarters of the foundation is glad to assist in supplying respirators for emergencies. Even with this assistance, the urgent need for respirators may not be satisfied. One community in the northern peninsula of Michigan solved the problem by constructing home made respirators from material commonly found in a carpentry or machine shop. Elsewhere in this issue of THE JOURNAL, in a report of the Council on Physical Therapy, additional information on emergency respirators is given. To conserve space, detailed specifications for construction are not published in THE JOURNAL, but they may be obtained for 10 cents by writing to the office of the Council on Physical Therapy at the American Medical Association in Chicago and requesting the pamphlet entitled "Simple Workable Respirators." Hospital authorities finding their budgets strained to the limit will welcome this information. Other institutions already equipped with respirators may wish to have the specifications in their files in case of emergency. These plans may be turned over to the maintenance department or the house carpenter for study, so that the person in charge will be familiar with them should an emergency arise. These home made respirators are not designed to take the place of efficient commercial acceptable respirators on the market but are offered as a means of tiding over an institution until more permanent equipment is made available.

MEDICAL PREPAREDNESS

In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medical preparedness, and such other information and announcements as will be useful to the medical profession.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

AN OPEN LETTER TO THE MEDICAL PROFESSION

The Office of the Procurement and Assignment Service has been flooded with thousands of enrolment forms and letters of inquiry. Present conditions make it impossible to acknowledge the receipt of enrolment forms or to answer the questions individually.

The office has been moved to 601 Pennsylvania Avenue N.W., Washington, D. C. Sufficient clerical assistants are difficult to obtain at this time.

All letters have been given personal attention and the questions have been clarified. The Committee on Information is preparing an article which should answer most questions. This will be ready for release in the very near future (probably February 21.—Ed.). This committee is also preparing a complete pamphlet of information on the organization, functions and activities of the Procurement and Assignment Service.

Many thousand enrolment forms have been processed; those who have volunteered for immediate service in the Army or the Navy will receive application blanks to be completed with a view of commission at an early date. The major portion of the time of this office is required for this purpose.

I would like to ask that all inquirers be patient with the thought that they will receive the answers to their questions and that the continued releases from this office will serve to keep them up to date. This should reduce materially the amount of correspondence. In this way the office will be relieved to the extent that it can provide personnel for the armed forces to meet the immediately expanding needs.

Questionnaires have been drawn up and enrolment forms are now being printed. These will be mailed to every physician, dentist and veterinarian within the near future. All information at hand as a result of previous questionnaires is being utilized. The additional data and the enrolment will serve to meet the future needs of the armed services and the governmental, industrial and civilian agencies which will require assistance.

I wish to express the appreciation of the Directing Board for the cooperation of the physicians, dentists and veterinarians which has made it possible for us to meet the military needs in such a short period of time.

MAJOR SAM F. SEELEY, M. C., U. S. Army.
Executive Officer, Procurement and
Assignment Service.

CHICAGO ORGANIZES EMERGENCY MEDICAL SERVICE

The Emergency Medical Service of the Office of Civilian Defense for the Chicago Metropolitan Area has completed its organization and now is functioning. Mayor Edward J. Kelly of Chicago, Metropolitan Coordinator, has announced. Dr. Herman N. Bundesen is chief of Emergency Medical Service and chairman of the Executive Committee of the Medical Advisory Council. Dr. Morris Fishbein is vice chairman of the Executive Committee. Other members are Dr. Raymond B. Allen, Dr. John S. Coulter, Mr. Joseph H. King and Dr. Malcolm T. MacEachern.

The chairmen of the various divisions of the Medical Advisory Council are as follows: Mr. King, Ambulance and Emergency Transportation; Dr. Sidney O. Levinson, Blood Transfusion and Blood Banks; Mr. O. U. Sisson, Drugs, Supplies and Equipment; Dr. Loyal Davis, First Aid Posts and Casualty Stations; Dr. MacEachern, Hospitals and Clinics; Dr. Harry E. Mock Sr., Health of Industrial Workers; Dr. Irving S. Cutter, Information; Miss Ada R. Crocker, R.N., Nurses' Aides; Mrs. Anna M. Fishbein, Nursing Care, Health of Women and Nutrition; Dr. H. Prather Saunders, Physicians; Dr. Walter H. Theobald, Shelters, Public Health and Morale, and Dr. James P. Simonds, Water Supplies.

As an example of the extent of the medical protection already created for the Chicago Metropolitan Area, the announcement says, in the event of an emergency ten thousand people from any one of the twenty-two zones established in the Metropolitan Area can be moved to a hospital within sixty minutes. An inventory of hospital facilities, equipment and personnel has

been completed and emergency medical field units have been established in practically all of the approved hospitals. First aid posts have been designated and the training of nurses' aides, under way for some time, is being constantly expanded. An inventory of supplies and necessary drugs in the Metropolitan Area is rapidly nearing completion, and four thousand drug stores in the area are available for supplying information to the public on the location of the nearest air raid shelters and medical facilities in the event of an emergency.

Steps have been taken for the safeguarding of the water supply in the area, both civilian and industrial, against contamination. These precautions involve not only the guarding of the sources of water supply but also such vital moves as the insuring of an adequate reserve supply of chlorine for the purifying of the water.

A survey is rapidly nearing completion of the day nurseries in the Metropolitan Area so that the Medical Advisory Council will be able adequately to take care of the children of employed mothers while they are at work.

A roster of physicians to man all the various medical operations of the Emergency Medical Service has been completed.

A miniature model casualty station to show the public how this phase of Emergency Medical Service will function, in the event of an emergency, is being made by Mrs. James Ward Thorne, noted miniaturist, and will be placed in the Museum of Science and Industry. The announcement says this will be the first model of its kind in the country.

It was announced that the following statement has been made by Dr. George Bachr, Chief Medical Officer of Civilian Defense, Washington, D. C.: "The recommendation of the United States Office of Civilian Defense has been adapted to the needs of

Metropolitan Chicago in so comprehensive a manner that the plans of the Medical Advisory Council of Chicago Metropolitan Civilian Defense Area may be accepted as a pattern for other large cities in the Middle West."

GENERAL HOSPITALS ORDERED INTO SERVICE

Present indications point to the activation of a number of reserve affiliated hospital units in the near future. The War Department has already ordered the activation of the Fourth, Fifth and Twenty-First Reserve General Hospitals and has ordered the Fifty-Second Evacuation Hospital to active duty. The Fourth General Hospital was organized by Western Reserve University Medical School, Cleveland, and has been ordered to active duty; the Fifth General Hospital by Harvard Medical School; the Twenty-First General Hospital by Washington University School of Medicine, St. Louis, and the Fifty-Second Evacuation Hospital was organized at Pennsylvania Hospital, Philadelphia. These units are made up of physicians and nurses serving at these hospitals; the officers have all been members of the medical reserve corps, while the nurses have been registered with the American Red Cross. Most of these units saw service in World War No. 1, at which time they were organized and equipped by the Red Cross, while now they are under the direct supervision of the Surgeon General of the Army as to organization and equipment.

CALL FOR BLOOD DONORS FOR THE ARMY

Although the army and navy forces in war areas now have blood plasma collected by the American Red Cross, even larger donations must be made if our forces are to be fully supplied with blood. Supplies of plasma have been delivered to the army and navy posts in the various Atlantic bases, the Philippines and throughout the Far East war area through the donations obtained by the American Red Cross. Col. Charles C. Hillman of the Surgeon General's Office, Washington, D. C., issued an urgent call on January 25 for additional blood donors. During the week of December 7 5,000 pints of blood in this country was volunteered in comparison with an average of about 1,000 pints during the period preceding the attack on Pearl Harbor. The goal of the Red Cross is to supply enough blood plasma not only for the army and navy but for civilian needs as well. The Red Cross has facilities already set up for the handling of hundreds of thousands of blood donations, and campaigns are under way to enroll additional civilian donors in sixteen of our largest cities.

CIVILIAN DEFENSE MEDICAL OFFICERS ON FIELD DUTY

Six medical officers have been appointed to Regional Offices of Civilian Defense to assist state and local defense councils in organizing Emergency Medical Service and carrying out the training and educational programs of the Medical Division. They have been commissioned as Senior Surgeons in the U. S. Public Health Service Reserve.

Dr. Allan M. Butler, First Civilian Defense Region, 101 Milk St., Boston, Mass.

Dr. H. Van Zile Hyde, Second Civilian Defense Region, 111 Eighth Ave., New York, N. Y.

Dr. W. Ross Cameron, Third Civilian Defense Region, 400 Cathedral St., Baltimore, Md.

Dr. William S. Keller, Fifth Civilian Defense Region, 427 Cleveland Ave., Columbus, Ohio.

Dr. W. Booth Russ, Eighth Civilian Defense Region, Majestic Bldg., San Antonio, Texas.

Dr. Wallace Hunt, Ninth Civilian Defense Region, 233 Sansome St., San Francisco, Calif.

CIVILIAN PROTECTION AREAS IN ILLINOIS

The chairman of the civil protection division of the Illinois state council of defense has announced the boundaries of the nine regions into which the state is to be organized for civil protection. The region boundaries in general follow the boundaries which have been fixed already for the state highway police operations. They have been subdivided into thirty-five warning districts, which vary in size according to the density of the population and of the industries within them. The plan provides that every rural section comprising 6 square miles will have an observation post and every town of two thousand five hundred or more population will have a report center. The chairman, Mr. William F. Waugh, announced the appointments of the liaison officers and others in the various regions.

SOUTH CAROLINA ORGANIZES EMERGENCY SERVICE UNITS

Representatives of every county in South Carolina met in Columbia on December 30 to plan the organization of emergency medical service units. The chief medical officer of the medical division of the South Carolina Council for National Defense, Dr. H. Grady Callison, presided. Among the speakers were Major G. Heyward Mahon, director of the South Carolina Council for National Defense; Lieut. Col. Ragnar E. Johnson, chemical officer at Fort Jackson; Dr. Floyd Rodgers, Columbia; Dr. Robert Wilson, Charleston; Dr. C. O. Bates, Greenville, and Dr. James A. Hayne, Columbia, state health officer. Among those present were medical officers for each of the eight medical districts of the state and the various county chief medical officers, as well as members of the state board of health, Drs. George Truluck and Dr. Thomas A. Pitts, president and president-elect, respectively, of the South Carolina Medical Association.

STUDENTS ENLISTING IN CLASS V-1, U. S. NAVAL RESERVE

Effective immediately, students in school or college who have not yet reached their twentieth birthday may enlist in class V-1 of the U. S. Naval Reserve and, on their own request, may be placed on inactive duty until the completion of the current scholastic year unless the military situation necessitates the Navy Department's calling them to active duty beforehand. Rear Admiral Randall Jacobs, U. S. Navy, Chief of the Bureau of Navigation, announced on January 22. Schools and colleges will be encouraged to give extra physical training and studies to young men who enlist in this category during the next four months as recommended by the Bureau of Navigation. The commandants of all naval districts have been directed not to call any of these men to active duty until orders have been issued by the Bureau of Navigation. In announcing the new opportunities for students, Rear Admiral Jacobs stated that naval recruiting will continue on a voluntary basis.

CONSULTANTS IN MEDICAL AND DRUG SUPPLIES

Dr. Robert P. Fischelis, chief chemist of the New Jersey Board of Pharmacy, member of the New Jersey Board of Health, has been released from those duties in order to give part time service as chief of the section of Medical and Health Supplies of the Civilian Supply Division of the War Production Board in Washington. Dr. Fischelis will organize a staff of consultants and specialists in hospital, medical and drug supplies. Their function will be to study civilian needs and plan for the allocation of health and medical supplies; also the problem of replacing drugs derived from foreign sources and now not available, and the possible replacement of certain drugs derived from scarce materials with drugs of similar therapeutic action derived from more plentiful sources.

ORTHOPEDIC MECHANIC POSITIONS OPEN

An examination has been announced by the Federal Civil Service Commission to secure orthopedic mechanics for the Army services. The salary is \$2,000 a year. Persons may qualify under the following optional subjects: (1) general, (2) bracermaker, (3) shoemaker and leatherworker and (4) limbmaker. Because of the demand for qualified eligibles, applications will be accepted at the Civil Service Commission's Washington office until further public notice.

Persons appointed will construct, design, alter and repair orthopedic appliances as indicated by the optional subjects. This includes working from living models and plaster casts, doing nickel plating, and shaping, grinding and polishing metals used in orthopedic appliances.

Applicants will not take a written test but will be rated on the extent and quality of their experience. They must have had five years of appropriate experience in orthopedic work within the past ten years. Under the option "shoemaker and leatherworker," persons whose experience has been in general shoe repair will not be considered qualified.

Examination announcements and application forms may be obtained at first and second class post offices and from the Civil Service Commission, Washington, D. C.

SOLDIERS' IDENTIFICATION TAGS

The War Department has revealed that the new identification tag worn by United States soldiers carries besides the soldier's name and serial number the name and address of the person to be notified in case of emergency, his religion, the date on which tetanus immunization was completed and his blood type. The present identification tag is made of stainless and rustproof monel metal, instead of aluminum as it was in the first World War; aluminum sometimes deteriorates as a result of chemicals and acids encountered on the battlefield. The present tag is 2 inches long, 1½ inches wide and .001 inch thick, with rounded corners.

AMBULANCES PRESENTED TO PHILADELPHIA

On behalf of the British American Ambulance Corps its president, Mr. William V. C. Ruxton, presented two ambulances on Dec. 18, 1941 to the mayor of Philadelphia for service with the mayor's civilian defense committee. The British American Ambulance Corps also presented two four stretcher ambulances to the city of San Francisco at the request of Mayor Angelo J. Rossi; these ambulances left New York on December 15. The British American Ambulance Corps is an American organization founded to relieve suffering and for months has sent to the British various urgently needed supplies. Now the ambulance corps is also actively engaged in defense work and the supplying of such needs of the American armies. The corps has sent ambulances to training camps in the United States and to newly acquired naval bases in Newfoundland and Iceland.

DEEP RED LIGHT BETTER THAN BLUE IN BLACKOUTS

Extensive experimentation by the army engineer corps reveals, the War Department announced on January 16, that a deep red light is much more satisfactory than the widely accepted blue light. Blue is more easily observed from the air than deep red, which also gives better illumination on the ground and aids the eyes to become adapted to the darkness. The disadvantage of using deep red, the announcement said, is the possibility of confusion with tail lights on motor vehicles; furthermore, since red illumination is not normal, it may, if not properly used, betray the installation which is to be concealed. All things considered, properly hooded low intensity white light is more generally applicable to blackout illumination problems than colored illumination.

CLEVELAND'S LAKESIDE UNIT ON ACTIVE SERVICE

The medical officers of U. S. Army General Hospital No. 4 left Cleveland on January 10 for active military service. The unit comprises physicians from Lakeside Hospital, City Hospital and other hospitals of Cleveland associated with Western Reserve University Medical School. The unit retains the number of its predecessor, which served in World War No. 1 with distinction at Rouen, France. Like the former hospital, which, the *Bulletin* of the Academy of Medicine of Cleveland says, was the first detachment of the American Expeditionary Forces to arrive in France, the present unit responded to the early call to military duty. When the entire personnel of the Lakeside Unit is assembled, it will number several hundred, including about fifty physicians, one hundred and twenty nurses, technicians, orderlies and cooks. The commanding officer is Col. William L. Starnes of the regular army medical corps; chief of the medical service is Lieut. Col. Joseph M. Hayman, professor of clinical medicine and therapeutics at Western Reserve University School of Medicine; the chief of the surgical service is Lieut. Col. William C. McCally, assistant clinical professor of surgery at Western Reserve. The head of the nursing staff is Miss Olga Benderoff, assistant director of nursing at University Hospitals, Cleveland. Seventy-two nurses assigned to Army Base Hospital No. 4 left Cleveland on January 19 en route to join the unit. The following additional physicians are members of the unit:

Surgical Service: Majors David A. Chambers, Donald M. Glover, James J. Joelson, John H. Lazzari and Wilbert H. McGaw. Capts. Sidney E. Blandford, Paul W. Gebauer, William Gernon, Carl A. Hamann, Donald A. Kelly, John J. Thornton, Vladimir L. Tichy, Elden C. Weckesser, Webb P. Chamberlain Jr. and Charles W. Elkins. First Lieuts. Cleon C. Couch, William W. Markley, Elmer P. Maurer, Ralph E. Gray and Valdemar M. Jordan.

Medical Service: Majors R. O. Egeberg, William R. Hal-laran, Edward O. Harper, Boyd G. King, William A. Read, Ralph L. Cox and Irwin Clay Hanger. Capts. Paul M. Glenn, Leo Walzer, Graham T. Webster, Walter M. Solomon, Frank M. McDonald, David R. Weir, L. H. Bronson and L. P. Longley. First Lieuts. James H. Donnelly, John P. Eichhorn, John R. McKay and Karl Rundell.

Laboratory Service: Major William B. Wartman, Capt. Joseph R. Kahn and First Lieut. H. H. Johnson.

Dental Corps: Capt. Henry J. Toomey and First Lieuts. Homer V. Briggie, Joseph W. Foltz, Anthony J. Tomaro, John E. McNally and Edward Ferreri.

Roentgenologic Service: Major Eugene Freedman, Capt. Joseph L. Morton and First Lieut. Isadore Meschan.

Administrative Service: Major Guy Brugler.

UNDERGRADUATE DEFENSE PROGRAM IN TRAINING NURSES

A three year undergraduate defense program for training student nurses in nine cooperating and affiliate schools is being administered by Wayne University, Detroit, with a \$48,690 fund granted to the university by the government. Miss Eleanor King, former instructor in nursing at Yale University and the University of California, has been named assistant coordinator of the three year program. The coordinator, Miss Louise Alfsen and Miss Eleanor King will give special attention to the training of nurses in communicable diseases and surgical and medical procedures.

MEDICAL AID FOR RUSSIA

The Springfield, Mass., Committee for Russian War Relief announced on January 22 through headquarters of Russian War Relief, Inc., 535 Fifth Avenue, New York, that Dr. Garry DeN. Hough Jr. of Springfield will head a group of medical men aiding the committee in its effort to get medical supplies to Russia; others in the group are Drs. Harold F. Budington, William A. R. Chapin, James B. Comins, Arthur E. F. Edgelow, Frederick S. Hopkins, Edward Katz, Roswell G. Mace, Oliver J. Menard, Mendel Poliak, Bernard Rabinovitz, Walter W. Williams, Charles F. Lynch, Joseph P. Derby and Salvatore Sannella.

EVACUATION HOSPITALS CALLED TO ACTIVE DUTY

The second and seventh evacuation hospitals have been called into active duty. The second, from St. Luke's Hospital, New York, reported to Fort Devens, Mass., and the seventh evacuation hospital from New York Post-Graduate Hospital, New York, was ordered to Fort Dix, N. J. The commanding officers of the two hospitals are Lieut. Col. William F. MacFee, M.D., and Lieut. Col. Robert S. Lobban, M.D., respectively.

MEDICAL SERVICE ON THE BURMA ROAD

According to the Christian Medical Council for Overseas Work, 156 Fifth Avenue, New York, the Quakers have provided the Burma Road in China with a modern medical service with Dr. Robert B. McClure in charge and Dr. Henry L. Louderbough and "Dr. Boyd from India" on the staff. About fifty young Englishmen act as chauffeurs. Trucks sent from the United States were assembled in Rangoon; fifteen trucks were fitted out as ambulances, which were used also to transport Red Cross supplies to Free China. The American Volunteer Group keep the road open by attacking Japanese bombers who fly over it from Indo-China.

ESTIMATE OF MEN KILLED IN THE PRESENT WAR

According to the statisticians of the Metropolitan Life Insurance Company, New York, deaths in the armed forces of all of the belligerent nations in the present war probably have reached at least 1,500,000 and may exceed 2,000,000. This estimate of losses is based on the compilation of analysis of data from sources which the Metropolitan Information Service believed most reliable. In the first World War the statisticians estimated that 5,000,000 men had been killed in a corresponding period; that is, the period of July 1914 to the end of 1916.

COLONEL GRANT APPOINTED AIR SURGEON

The post of air surgeon in the U. S. Army was recently created, the War Department announced recently, and Col. David W. Grant, M.C., was the first officer assigned to the new position. The air surgeon, who will be a member of the staff of the chief of the Army air forces, will be head of a service to coordinate the medical activities in the air service. In Colonel Grant's case, this duty will be in addition to that performed by him as chief of the medical division, office of the chief of the air corps.

EMERGENCY MEDICAL FIELD SETS

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, during January has given eight emergency medical field sets to the medical directors of the second civilian defense region (New York, New Jersey, Delaware) and also one set each to Chicago, Minneapolis and Reno. The membership in the Medical and Surgical Relief Committee of America has been augmented in the last three months by the names of thirty-three physicians, bringing the total membership to three hundred and fifty-one.

SPECIAL DEFENSE PROJECTS AT WAYNE UNIVERSITY

As an outgrowth of the defense program, Wayne University College of Medicine, Detroit, has undertaken several special projects, among which are the preparation of an index of the literature on military medicine covering the period from 1939 to date, a study of "shock" and a special study of "bacteriologic aspects of wound infections." The index has already been microfilmed by the Army Medical Library for military use.

ERIE ORGANIZES EMERGENCY SQUADS

The medical defense committee of Erie, Pa., of which Dr. Arthur G. Davis is chairman for the local medical society, has organized eight emergency medical field units and established evacuation medical centers in each of the wards of the city. Each squad comprises four physicians, one dentist and four nurses. Four squads have been assigned to the Hamot and four to St. Vincent's Hospital. These hospitals also have organized emergency teams for the care of the injured after they reach the hospital, where emergency beds have been made available. These emergency squads and evacuation centers have already held several practice sessions.

THE O'REILLY GENERAL HOSPITAL

Col. George B. Foster, M. C., has been assigned as commanding officer of the new thousand bed O'Reilly General Hospital of the U. S. Army, which was recently dedicated at Springfield, Mo.; Lieut. Col. Allan W. Dawson, M. C., U. S. Army, has been assigned as executive officer.

MEETING OF SELECTIVE SERVICE AND INDUCTION BOARD PHYSICIANS

The Maryland Society of Selective Service and Induction Board Medical Examiners held a meeting in Baltimore, January 30, with Dr. Sydney R. Miller presiding. Albert C. Gakenheimer gave a demonstration of equipment for administration of blood plasma, Lieut. Col. Amos R. Koontz, M. C., discussed the new local board examination plan and Major Henry M. Thomas Jr., M. C., experience on the medical service of a station hospital.

JEFFERSON COUNTY ALABAMA FIRST AID STATIONS

Fifty physicians have been assigned to supervise the first aid stations in the twenty-one air raid warden areas in Jefferson County, Ala., in which Birmingham is located. The selections were made by the chief of the civilian defense emergency medical service, Dr. H. Earle Conwell, Birmingham, and approved by the director of the civilian defense council. The fifty physicians, in addition to supervising first aid stations, will have charge of the transportation of wounded in case of air raids or other disaster.

SYMPOSIUM ON NUTRITION

An exhibit on army nutrition and a symposium for reserve officers will be held Jan. 13, 1942, in the Federal Building, 90 Church Street, New York City, at 8:30 p. m. The speakers will be Cols. Samuel Adams Cohen and H. I. Teperson of the medical reserve, Lieut. Col. James A. Tobey of the Sanitary Corps Reserve and Major Louis Griesman of the Veterinary Corps Reserve. The program is under the supervision of Lieut. Col. William C. Lippold, M. C., U. S. Army, and the chairman of the executive committee, Col. Milton I. Strahl.

LECTURE ON CHEMICAL WARFARE

Col. Curtis Claassen, M. C., U. S. Army, addressed the medical staff of Mount Sinai Hospital, New York, and the medical officer personnel of the Third General Hospital, U. S. Army, February 10, on "Defense Against Chemical Warfare and the Treatment of Gas Casualties."

SOLDIERS FORBIDDEN TO HITCH-HIKE

The War Department reminded all men in uniform January 18 that the solicitation of free rides is prohibited as being unmilitary and in some states unlawful. However, the War Department permits soldiers to accept offers of rides voluntarily made by individuals or organizations.

ARMY RESERVE OFFICERS ORDERED TO ACTIVE DUTY SECOND CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Second Corps Area, which comprises the states of New York, New Jersey and Delaware.

DANGERFIELD, Harold 1st Lieut, Staten Island, N Y, Camp Lee, Va
FAZIO, Michael G, 1st Lieut, Brooklyn, Fort Dix, N J
GRUSKIN, Harry, 1st Lieut, Brooklyn, Fort Tilden, N Y
ISRAEL, Benjamin, 1st Lieut, New York, Camp Lee, Va
KAPLAN, Lawrence G, 1st Lieut, Forest Hills, L I, N Y, Fort Wadsworth, N Y
KLINE Ernest Hall, Captain, New York, Fort Hancock, N J
KUFLIK, William E, 1st Lieut, Brooklyn, Fort Wadsworth, N Y
LABARBERA, Thomas, 1st Lieut, Brooklyn, Fort Dix, N J

LEVINE Bernard R, 1st Lieut, New York, Fort Wadsworth, N Y
LITTMAN, Julius Kiva, 1st Lieut, New York, Camp Lee, Va
MANNING, Ephraim L, 1st Lieut, Yonkers, N Y, Camp Lee, Va
McDONNELL, George J, 1st Lieut, Freehold, N J, Fort Hancock, N J
MILES, Anthony W, 1st Lieut, Brooklyn, Fort Wadsworth, N Y
PAPPALARDI, Felix A, 1st Lieut, New York, Fort Hancock, N J
SEAMAN, George J, 1st Lieut, Brooklyn, Fort Dix, N J
SHERMAN, Pincus, 1st Lieut, New York, Pine Camp, N Y
SHIFFMAN, Morris, 1st Lieut, New York, Headquarters 2d Military Area
SIMON, Charles, 1st Lieut, Brooklyn, Fort Niagara, N Y
WARNOCK, George H, 1st Lieut, Freeport, L I, N Y, Fort Sheridan, Ill
WEISS, Bernard, 1st Lieut, Poughkeepsie, N Y, Fort Niagara, N Y
WYCOFF, Joseph W, 1st Lieut, Hicksville, N Y, Fort Monmouth, N J

FOURTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Fourth Corps Area, which comprises the states of Tennessee, North Carolina, South Carolina, Alabama, Georgia, Mississippi, Florida and Louisiana:

BOOKER, John Parks, 1st Lieut, Walhalla, S C, Camp Gordon, Ga
HOLBROOK, Joseph Samuel, 1st Lieut, Statesville, N C, Camp Bland-
ing, Fla
HULL Wallace A, 1st Lieut, Indianola, Miss, Camp Tyson, Tenn
JENKINS, Hughes B, Major, Donaldsonville, Ga, Camp Gordon, Ga
LAIRD, Earl Lee, 1st Lieut, Union, Miss, Camp Gordon, Ga
LANCASTER, Lamar L, 1st Lieut, Bartow, Fla, Camp Gordon, Ga
LOBRANO, Charles M, 1st Lieut, Memphis, Tenn, Fort McPherson, Ga
MASON, James M, III, 1st Lieut, Birmingham, Ala, Fort Bragg, N C

TUCKER, Landrum S, 1st Lieut, Rogersville, Tenn, Camp Tyson, Tenn
VINSANT, Lowell Eugene, 1st Lieut, Knoxville, Tenn, Camp Gordon, Ga
WEATHERLY, George Irving, Jr, 1st Lieut, Fort Payne, Ala, Camp Forrest, Tenn
WOLFE, Albert B, 1st Lieut, Orangeburg, S C, Camp Gordon, Ga

Orders Revoked

BRANTLEY, James W, 1st Lieut, Grandin, Fla
BURTON, John Paul, 1st Lieut, New Orleans
GEORGE, Wallace E, 1st Lieut, West Columbia, S C
JAFTE, Bernard, 1st Lieut, Asheville, N C
LOGAN, James G, 1st Lieut, Natchez, Miss
NAUGLE, Thomas C, 1st Lieut, East Gadsden, Ala
NELSON, Thomas F, 1st Lieut, Tampa, Fla
ROZIER, John Simpson, 1st Lieut, Leesville, La
SHIPP, Larry G, 1st Lieut, Anniston, Ala

FIFTH CORPS AREA

The following named Medical Reserve officers were ordered to extended active duty by Fifth Corps Area order for the week ending January 16, 1942:

BECKER, William, 1st Lieut, Toledo, Ohio, Fort Knox, Ky
CHAMBERLAIN, Webb P, Jr, Captain, Cleveland, Fort Hamilton, N Y
ECKSTEIN, Richard W, 1st Lieut, Cleveland Erie Proving Ground
ELKINS, Charles W, Captain, Lakewood, Ohio, Fort Hamilton, N Y
HANGER, Irwin C, Major, Beechwood Village, Ohio, Fort Hamilton, N Y
HARVEY, Bennett B, 1st Lieut, Indianapolis, Camp Grant, Ill
HOY, Robert T, Jr, 1st Lieut, Fort Thomas, Ky, Fort Thomas, Ky
IMBURGIA, Frank J, 1st Lieut, Marion, Ind, Fort Benjamin Harrison, Ind
JOHNSON, Herbert H, Jr, 1st Lieut, Cleveland, Fort Jackson, S C

JORDAN, Valdemar M, 1st Lieut, Cleveland Heights, Ohio, Fort Hamilton, N Y
OLSEN, Albert L, Captain, Marion, Ind, Fort Hayes, Ohio
ROSSMILLER, Harold R, 1st Lieut, Cleveland, Fort Benjamin Harrison, Ind
RUNDELL, Kail D, 1st Lieut, Owego, N Y, Fort Jackson, S C
SWANN, Lyndon Bernard, 1st Lieut, Louisville, Ky, Erie Proving Ground, Lacrosse, Ohio
TANNO, Anthony M, 1st Lieut, Cleveland, Fort Benjamin Harrison, Ind

Orders Revoked

JASKIEWICZ, Casimir F, 1st Lieut, Logan, W Va
MORRISON, William H, 1st Lieut, Howe, Ind
PETRO, George J, 1st Lieut, Louisville, Ky
TOUPKIN, Jerome H, 1st Lieut, Raleigh, W Va
WILSON, Orley E, 1st Lieut, Elkhart, Ind

SEVENTH CORPS AREA

The following additional medical reserve corps officers have been ordered to extended active duty by the Commanding General, Seventh Corps Area, which comprises the states of North Dakota, South Dakota, Minnesota, Nebraska, Iowa, Kansas, Missouri, Arkansas and Wyoming:

BIZZELL, Ross, 1st Lieut, Little Rock, Ark, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
CASH Paul Thibault, 1st Lieut, Omaha, Corps Area Service Command Station Hospital, Fort Omaha, Neb
HUNDLEY, Louis King, Captain, Fayetteville, Ark, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
LAWSON, Mason Glynn, 1st Lieut, Texarkana, Ark, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
MINER, Paul Floyd, 1st Lieut, Laramie, Wyo, Corps Area Service Command Station Hospital, Fort Francis E Warren, Wyo
RADI Robert Bernard, Major, Bismarck, N D, State Headquarters Selective Service, Bismarck, N D
RIGGINS Winston Calaway, 1st Lieut, Little Rock, Ark, Corps Area Command Service Station Hospital, Camp J T Robinson, Ark

SETTLE, Emmett Bird, Captain, Rockport, Mo, Corps Area Service Command Station Hospital, Fort Leavenworth, Kan
WILLIAMS, John Westerfield, 1st Lieut, Springfield, Mo, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo

Orders Revoked

FREEDLAND, Morris E, 1st Lieut, Minneapolis
FROGNER, Lester E, 1st Lieut, Grand Marais, Minn.
HARTWIG, John A, Captain, St Louis

Relieved from Active Duty

BAKER, Joseph Harrison, Captain, LaCrosse, Wis, Corps Area Service Command Station Hospital, Fort Riley, Kan
GANSCHOW, John Henry, 1st Lieut, Hedrick, Iowa, Corps Area Service Command Station Hospital, Fort Leonard Wood, Mo
LUEDEDE, Philip Shrock, Captain, St Louis, Corps Area Service Command Station Hospital, Camp J T Robinson, Ark
MILLER, Richard White, 1st Lieut, Fayetteville, Ark, Army and Navy General Hospital Hot Springs, Ark
ZELIGS Isadore 1st Lieut, Iowa City, Corps Area Service Command Station Hospital, Fort Riley, Kan

EIGHTH CORPS AREA

The following additional medical reserve corps officers have been ordered to active duty by the Commanding General, Eighth Corps Area, which comprises the states of Colorado, Arizona, New Mexico, Oklahoma and Texas:

BAILEY, William M, Lieut Colonel, Tyler, Texas, Recruiting Station, Sante Fe, N. M.
BOGUSKIE, William M, Captain, Hearne, Texas, Corps Area Service Command, Camp Barkley, Texas
DAVIS, James H, Colonel, Fort Worth, Texas, Recruit Reception Center, Camp Wolters, Texas
FIEGEL, Walter L, 1st Lieut, Lewisville, Texas, Station Hospital, Fort Sill, Okla
FIELDING, Lewis J, 1st Lieut, Waco, Texas, District Recruiting Office, Phoenix, Ariz
FOWLER, Harmon L, Colonel, Denver, Recruit Reception Center, Fort Bliss, Texas
GAMBRELL, James H, Colonel, El Paso, Texas, Station Hospital, Camp Barkley, Texas
GLOVER, George E, Lieut Colonel, Austwell, Texas, Recruit Reception Center, Fort Sam Houston, Texas
KELLER, Louis, 1st Lieut, Whipple, Ariz, 45th Division, Camp Barkley, Texas
LAWRENCE Gerald P, Colonel, Mayhill, N. M., Reception Center, Fort Sill, Okla

LEVINE, Milton, Captain, Fort Bayard, N. M., 36th Division, Camp Bowie, Texas
LEWIS, W. B., Colonel, Denver, Colorado Recruiting District, Fort Logan, Colo
MATTS, Robert M, Captain, Yuma, Ariz, 25th Infantry, Fort Huachuca, Ariz
POORE, Alfred M, 1st Lieut, Waco, Texas, Station Hospital, Fort Sill, Okla
ROBERTSON, Robert C. L., 1st Lieut, Houston, Texas, Station Hospital, Fort Sam Houston, Texas
SHADDIX, James W., Lieut Colonel, Shamrock, Texas, Recruiting Station, Lubbock, Texas
SHIELDS, Thomas L., 1st Lieut, Dallas, Texas, 2d Infantry Division, Fort Sam Houston, Texas
STUCK, Ralph M, 1st Lieut, Denver, Station Hospital, Fort Bliss, Texas
WILHITE, Lee Roy, Colonel, Perkins, Okla, U. S. Army Recruiting Station, Houston, Texas

Orders Revoked

BARSH, Albert G, 1st Lieut, Stephenville, Texas.
DAVIS, Robert L, 1st Lieut, Williams, Ariz
KILMAN, Prather T, Captain, Malakoff, Texas
KINSINGER, Ralph R, 1st Lieut, Blackwell, Okla
MCCURDY, William C, Jr, 1st Lieut, Purcell, Okla.
MCGEEHEE, Frank O, 1st Lieut, Memphis, Tenn
PRESTON, Thomas K, 1st Lieut, Muskogee, Okla.
SALMON, George W, 1st Lieut, St. Louis
SCIRE, Feliciano J, 1st Lieut, Keams Canyon, Ariz.

ORDERED TO FOREIGN DUTY

[Some of these orders were issued prior to Dec. 8, 1941]

ANDERSON, Vetalis Vernon, 1st Lieut, Fort Bliss, Texas, 200th Coast Artillery (Antiaircraft), Fort Stotsenburg, Philippine Islands
ANDLER, Maxwell M, Jr, 1st Lieut, Brookline, Mass, 12th Medical Regiment, Fort William McKinley, Philippine Islands
BARNES, Louis Dwight, Major, 57th Infantry, Fort William McKinley, Philippine Islands
BARSHOP, Nathan, Captain, Los Angeles, Station Hospital, Fort Stotsenburg, Philippine Islands
BLOOM, Manuel Gordon, 1st Lieut, Houston, Texas, Station Hospital, Fort Mears, Dutch Harbor, Alaska
BOLTON, Leslie Turner, Lieut Colonel, Reno, Nev., Headquarters Philippine Department Fort Santiago, Manila, Philippine Islands
BULFAMONTE, Joseph Charles, 1st Lieut, Fort William McKinley, Philippine Islands
BURGE, Julius Caesar, Jr, 1st Lieut, York S. C., Station Hospital, Fort William McKinley, Philippine Islands
CARTER, James Weldon, 1st Lieut, Lubbock, Texas, Fort Amador, Balboa, Canal Zone
CHOISSER, John Elder, Lieut (j. g.), M. C. V. (G) N. R., Eldorado, Ill., U. S. S. *Boise*, Pearl Harbor, Hawaii
COCHRAN, Joel Layton, Major, Camp Wolters, Texas, Fort Amador, Balboa, Canal Zone
COLBY, Elliott Gillette, Lieut Colonel, N. G., San Diego, Calif., 251st Coast Artillery (Antiaircraft), Camp Malakole, Hawaii
COLVARD, George Todd, Major, N. G., Fort Bliss, Texas, 200th Coast Artillery (Antiaircraft), Fort Stotsenburg, Philippine Islands
COMSTOCK, Jack Arthur, 1st Lieut, Denver, Sternberg General Hospital, Manila, Philippine Islands
CONLAN, Francis Joseph, 1st Lieut, San Francisco, Station Hospital, Fort Mears, Dutch Harbor, Alaska
DOBIAS, Stephen Glenn, 1st Lieut, Fort Leavenworth, Kan., Fort Greely, Kodiak, Alaska
DONNELLY, Verner Judson, Lieut (j. g.), M. C. V. (G) N. R., Plainview, Texas, U. S. S. *Minneapolis*, Pearl Harbor, Hawaii
FLOCKS, Milton, 1st Lieut, Baltimore, U. S. Engineers, Borinquen Field, Puerto Rico
FOLSON, Charles Walton, Captain, Sternberg General Hospital, Manila, Philippine Islands
GARRETT, Robert Thompson, 1st Lieut, Southampton, N. Y., Hickam Field, Hawaii
GLUSMAN, Murray, Lieut (j. g.), M. C. V. (S) N. R., New York, Dispensary, Navy Yard, Cavite, Philippine Islands
HALL, Joseph Leslie, 1st Lieut, Fort William McKinley, Philippine Islands
HANKINS, Charles Robert, 1st Lieut, Fort Leonard Wood, Mo., Sevard, Alaska
HELSTIEY, Gordon Friedrich, Lieut Colonel, N. G., Fresno, Calif., Fort Greely, Kodiak, Alaska
JACOB, Samuel Sprigg, III, Captain, Station Hospital, Corozal, Canal Zone
JORDAN, Fred Covington, Jr., 1st Lieut, Phoenix, Ariz, Fort Ruger, Honolulu, Hawaii
JULIA, Carlos M., Captain, N. G., Rio Piedras, Puerto Rico, Camp Tortuguero, San Juan, Puerto Rico
KELLY, Alex Rennie, Jr., 1st Lieut, Camp Davis, N. C., Station Hospital, Fort William McKinley, Philippine Islands
KESCHNER, Harold Walton, 1st Lieut, New York, Sternberg General Hospital, Manila, Philippine Islands
MCGUIGAN, Robert Alister, Lieut (j. g.), M. C. V. (G) N. R., Evanston, Ill., U. S. S. *Dobbin*, Pearl Harbor, Hawaii
MOONEY, Robert Davis, 1st Lieut, Station Hospital, Fort Richardson, Alaska
OLIVER, Claudius Hansen, Lieut Colonel, San Antonio, Texas, Fort Davis, Canal Zone
OSBORNE, Charles Eugene, 1st Lieut, Camp Wheeler, Ga., Fort Stotsenburg, Philippine Islands
PASSALACQUA, Luis Antonio, Captain, N. G., Ponce, Puerto Rico, Station Hospital, Losey Field, Ponce, Puerto Rico
PHILLIPS, Claude Mason, Captain, San Antonio, Texas, Camp Paraiso, Canal Zone
RAMSAY, Lewis Cowan, 1st Lieut, Medical Department, 804th Engineers, Schofield Barracks, Honolulu, Hawaii
SERVOSS, Spencer Joseph, 1st Lieut, Medina, N. Y., Medical Dispensary, Albrook Field, Canal Zone

WALKER, Price Mars, Major, Dallas, Texas, Station Hospital, Schofield Barracks, Honolulu, Hawaii
WHITE, William Alvin Jr, Lieut (j. g.), M. C. V. (G) N. R., Cincinnati, Ohio, Naval Hospital, Pearl Harbor, Hawaii

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. 2240 has been ordered reported by the Senate Committee on Military Affairs, proposing to establish a Women's Army Auxiliary Corps for service with the Army of the United States. H. R. 3539, has passed the House and is pending in the Senate with a favorable committee report providing, in effect, that revenue derived from the operation of Indian Service hospitals in Alaska shall be available for expenditure for the benefit of such hospitals.

Bills Introduced.—H. R. 6521, introduced by Representative Beiter, New York, proposes to extend the benefits of the Soldiers' and Sailors' Civil Relief Act in connection with mortgages and instalment contracts to transactions originating subsequent to Oct. 17, 1940. Under existing law relief is provided by the act only with respect to such transactions originating prior to the date named. H. R. 6524, introduced by Representative Secrest, Ohio, proposes to increase the federal appropriation available to provide books for the adult blind. H. R. 6525, introduced by Representative Voorhis, California, provides compensation for personnel sustaining disease or injury while performing civilian defense duty.

STATE MEDICAL LEGISLATION

Kentucky

Bills Introduced.—S. 76 proposes to prohibit the operation of any hospital or clinic, whether private or governmental, without a license to do so from the state board of health. H. 144 proposes to enact a practice act for dental hygienists to be administered by the state board of dental examiners. "Dental hygiene" is defined in the bill to mean the treatment of human teeth by removing therefrom calcareous deposits, and by removing accumulated accretion from directly beneath the free margin of the gums, and by polishing the exposed surface of the teeth.

Mississippi

Bills Introduced.—H. 231 proposes to authorize counties, cities and towns, separately or jointly, to own, erect, maintain and operate hospitals, and to levy taxes to raise necessary funds for such purposes. H. 361 proposes to authorize the board of supervisors of the various counties in the state to levy annually, in addition to the levy for indigent sick, a special tax of not exceeding 1 mill on all the taxable property of the county to raise sufficient funds for necessary medical, dental or other treatment to children up to 16 years of age in need of and unable to procure care. H. 298, to amend the law creating a state hospital commission to reimburse certain approved hospitals for hospital care rendered indigent patients, proposes to abolish the state hospital commission provided for therein and to provide in lieu thereof for the appointment of a state hospital commissioner by the state board of health and to vest all of the power and authority now vested in the state hospital commission in that commissioner.

South Carolina

Bill Introduced.—S. 980, to amend the uniform narcotic drug act, proposes (1) to define narcotic drugs so as to include cannabis in addition to "coca leaves, opium, and every substance neither chemically nor physically distinguishable from them," the definition in the present law, and (2) that the provisions of the act shall not apply to the administering, dispensing or selling at retail of any medicinal preparation that contains in 1 fluid ounce, or if a solid or semisolid preparation, in 1 avoirdupois ounce, not more than 1 grain of codeine or of any of its salts. The present law provides a similar exemption with respect to

preparations which in the quantities stated do not contain more than 2 grains of opium, $\frac{1}{4}$ grain of morphine, 1 grain of codeine, or $\frac{1}{8}$ grain of heroin.

New York

Bills Introduced.—S. 245 and A. 288 propose to provide for the reimbursement by the state to each public welfare district for hospital care rendered to patients suffering from tuberculosis. S. 491 proposes to require the board of education in each city of the state to establish, maintain and equip a permanent staff of physicians, psychiatrists, dentists, dental hygienists and nurses for the periodic examination and promotion of the health of the children of school age in such city. S. 523 proposes to require every local board of health and every health officer to exercise proper and vigilant medical inspection of all persons 21 years of age or over, infected with poliomyelitis and, after approval by the state commissioner of health, provide at the remedial stages of the disease suitable surgical, medical or therapeutic treatment or hospital care, and necessary appliances and devices for such persons so infected or exposed who cannot otherwise be provided for. One half of the cost of providing the necessary treatment, care and appliances is made a charge against the county, or the city of New York, as the case may be, in which such person resides, and the remaining one half is to be paid by the state. A. 604 proposes to authorize the establishment and operation of a psychiatric bureau as an adjunct of the children's court in any county, for the physical, mental and psychiatric examination of persons within the jurisdiction of the court. Any such bureau shall be staffed with one or more competent psychiatrists and others, in accordance with appropriate authorization, who shall be appointed by the judge of the court and serve under his direction.

New Jersey

Bill Introduced.—S. 10, to amend the dental practice act, proposes, among other things, that the act shall not apply to the treatment of the diseases of the mouth and practice of oral surgery in the practice of his profession by a physician or surgeon licensed under the laws of the state, unless he undertakes to reproduce or reproduces lost parts of the human teeth in the mouth or to restore or replace lost or missing teeth in the mouth. Under the present law, apparently, the act, as far as the practice of licensed physicians and as far as specific language is concerned, does not apply to the rendering of dental relief in emergency cases by a physician in the practice of his profession.

Virginia

Bills Introduced.—S. 110, to amend the medical practice act, proposes to increase the per diem remuneration to be paid to members of the board of medical examiners to \$10 and to increase the annual salary of the secretary of the board to \$2,000. H. 166, to supplement the medical practice act, proposes to make it unlawful for any person to engage in the practice of medicine in the state without first having obtained from the board of medical examiners the necessary license or certificate and without first having recorded the license or certificate with the clerk of the appropriate court. H. 195 proposes to enact a separate chiropractic practice act and to create an independent chiropractic board of examiners to examine and license applicants for licenses to practice chiropractic. The bill proposes to define chiropractic as "the adjustment of the twenty-four movable vertebrae of the spinal column and other articulations, and assisting nature, for the purpose of facilitating the transmission of nerve energy." The bill proposes that a chiropractic licensee may use such methods as are taught by chiropractic schools and colleges to further

assist nature in establishing the normal transmission of nerve energy, but is prohibited from practicing operative surgery, obstetrics, osteopathy, and from administering or prescribing any drug or medicine. Such a licensee is to be permitted to use the title "Dr." in connection with his name when accom-

panied by the word "chiropractor" or the letters "D.C." S. 120 proposes to prohibit any institution of learning in the state, unless accredited by the state board of education, from conferring any college degree, whether academic, professional or honorary.

MEDICAL ECONOMIC ABSTRACTS

JAPAN'S RESOURCES

While Japan demands greater space for her population, she bends all her energies to increasing that population. Moreover, industrial and general social conditions maintain that threaten to destroy the producing power of the population. The statisticians of the Metropolitan Life Insurance Company, after a study of Japan's population conditions, point to a rather abrupt reversal from a fairly rapid increase to a pronounced decline about 1935. Then the cabinet, early in 1941, entered on a program which aimed to increase Japan's population from its present figure of seventy-three million to a hundred million in 1960. This plan offers subsidies to large families with corresponding penalties to small families and unmarried persons.

While Japan has eleven million men in the principal military age, 20 to 44, the United States has a reserve of more than double that number. This is due not only to our greater total population but to the fact that the United States has 38.5 per cent of its male population in this military age group while Japan has only 34 per cent. The general death rate in Japan is comparable to that in the United States forty years ago. While the tuberculosis death rate in this country is 45 per hundred thousand, it was 204 per hundred thousand in Japan in 1937.

Another side of the picture is seen in the world economic survey of the League of Nations published in this country by the University of Columbia Press. This shows that even in 1939 Japan was beginning to show signs of fatigue in her economic system. In the early part of that year "it was recorded, for instance, that a considerable increase in the number of fires in factories in the Tokyo area was largely due to the excessive fatigue of the workers. Moreover, the statistics of sickness, accidents and absence from work began to rise. Accordingly, on March 31, 1939 the government issued an order for the protection of workers employed in branches of industrial activity where work necessitated by the requirements of national defense was carried on. This order, fixing a maximum working day of twelve hours, came into effect on May 1. In the spring of 1938 a 'National General Mobilization Law' was enacted with the object of increasing the supply and efficiency of labor and of raising the productivity of industrial equipment. In April 1940 a Japanese source stated that it was 'doubtful' whether the result had been 'satisfactory.' 'Labor efficiency,' it said, 'has lately become strikingly low.'

"The material equipment was likewise deteriorating. Plant and machinery were wearing out and could not be adequately replaced; and this consumption of capital was taking place not only in the 'inessential' consumer trades but also in the armament industries." As a result of these conditions, the survey

points out that as "Japan has been at war continuously since the middle of 1937 she has had time to organize her war economy to the limit of her capacity; and yet in 1940-41 she was not able to extract much more than a quarter of her national income for war purposes. In a relatively poor country, obviously the margin between total production and the subsistence minimum of consumption is narrow."

NEW MORTALITY RECORD

In spite of a minor influenza epidemic and the dislocation of the population as a result of national defense efforts, the statisticians of the Metropolitan Life Insurance Company declare that the 1941 death rate of 7.4 per thousand was the lowest ever attained in any year by their company's millions of industrial policyholders, and, as a result, the expectation of life of these insured persons was advanced to 63.4 years, a gain of some six months over the 1940 figure of 62.9 years.

Owing largely to the sharp rise in motor vehicle fatalities, the death rate from accidents—all forms—increased. The motor vehicle fatality rate of 1941, 20.8 per hundred thousand, was 14.3 per cent above that of 1940 and the highest since 1937.

When the United States entered the first world war in 1917 the statisticians explain that the death rate among insured persons was 11.6 per thousand, or more than half as high again as that recorded for 1941.

The pneumonia death rate, as the result largely of the use of sulfonamide derivatives, dropped to the new low level of 30.5 per hundred thousand, which compares with 35.5 in 1940, 42.8 in 1939, 50.6 in 1938 and 66.9 in 1937. Prior to 1937 the pneumonia mortality rate had never fallen below 60 per hundred thousand.

Second only to the improvement in pneumonia mortality conditions was the situation with respect to tuberculosis, the death rate of which once more dropped to a new low point, as it has many times in recent years.

An interesting development with respect to tuberculosis has resulted in connection with the Selective Service Act. "As the rejections for respiratory diseases—largely tuberculosis—are but little below those in the last war," the statisticians explain, "while mortality from the disease has declined 77.3 per cent, it appears that a good job of early case finding is being done."

New minimal rates were also recorded last year for scarlet fever, diphtheria, appendicitis and diseases of the puerperal state. A minimum low maternal mortality rate occurred despite a sharp rise in the number of women exposed to the hazards of pregnancy and childbirth, since the birth rate in 1941 was the highest on record since 1930.

WOMAN'S AUXILIARY

California

The medical society is cooperating with the Alameda County woman's auxiliary in furnishing speakers for organizations requesting talks on medical subjects. It in turn has asked the auxiliary to be ready to assist the society by furnishing a telephone committee to handle appointments for volunteer donors to the San Francisco blood bank.

The outstanding activity at present in the San Francisco County auxiliary is that of sponsoring a day at the San Francisco Hospitality House, located in the Civic Center. The auxiliary is planning on providing at least three hundred young men with food and amusement during the day. The building

will be staffed that day with auxiliary members. The training schools of Stanford and of the University of California have been asked to cooperate with the doctors' wives by sending twenty-five girls from each of these schools. The girls will be called for and delivered back to their dormitories by members of the auxiliary. Mrs. Wilber Swett, general chairman, will be assisted by Mrs. Raleigh Burlingame, Mrs. John Humber, Mrs. John J. Loutzenheiser, Mrs. Roger B. McKenzie and Mrs. William A. Sumner.

At a recent meeting of the Woman's Auxiliary to the San Diego County Medical Society one hundred and one members and guests were served at luncheon. Invitations were issued to wives of Army and Navy physicians new in the community.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

New Health Center.—A new health and welfare center will soon be constructed in Tucson, according to the *Arizona Public Health News*. Health and welfare agencies will be housed in the new building, the architect's plans for which have already been approved.

Changes in Health Officers.—Dr. Abe L. Scheff, formerly of Rosedale, Miss., passed assistant surgeon, U. S. Public Health Service, reserve, has been appointed director of the Santa Cruz Health Service, which on January 1 ceased to be a part of Health District Number 1. According to the *Arizona Public Health News* the importance of Nogales and Santa Cruz County in the present emergency and the development of needed health services make a full time resident director necessary. —Dr. Robert M. Matts, Yuma, director of the Yuma County Health Service, has been called into active service.

CALIFORNIA

Library on Plastic Surgery.—On December 12 a collection of fifty-seven books on plastic surgery was received by the Library of the Los Angeles County Medical Association, Los Angeles, under a bequest in the will of the late Dr. Howard L. Updegraff, Los Angeles. The gift included also a group of famous medical caricatures. The books date from 1528 to 1939 and include "The Proportion of Human Anatomy," published by Albrecht Dürer in Nuremberg in 1528, and a volume of Celsus' work, also published in 1528 by the Aldine Press. The most recent of the group is "The Surgery of Injury and Plastic Repair" (Dr. Samuel Fomon) 1939.

Santa Monica Hospital Dedicated.—The Santa Monica Hospital was dedicated on January 4 as a unit of the Lutheran Hospital Society of Southern California. This hospital was turned over to the California Hospital, Los Angeles, operated by the society, early in January 1941, fulfilling the plans of Dr. William S. Mortensen, president and medical superintendent of the Santa Monica Hospital, to convert his corporation into a nonprofit institution for the citizens of Santa Monica. With Dr. Mortensen, Mrs. Hromadka, widow of Dr. August B. Hromadka, arranged the gift as a trust to the Lutheran Hospital Society, and the recent ceremonies dedicated the hospital as a memorial to the two physicians.

COLORADO

Society News.—The Pueblo County Medical Society was recently addressed by Drs. Harold T. Low and Harry E. Coakley, Pueblo, on "Congenital Intravesical Obstruction in Male Children." —Dr. Roy P. Forbes, Denver, discussed "Frequent Mistakes in Diagnosis" before the Weld County Medical Society in Greeley recently.

The Sewall Lecture.—Dr. Maurice C. Pincoffs, professor of medicine, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, delivered the Henry Sewall Memorial Lecture, February 3, in the Denison Memorial Auditorium, Denver, during the annual meeting of the Medical Society of the City and County of Denver. His subject was "Epidural Abscess."

ILLINOIS

Newspaper Cooperates in Mental Hygiene Project.—The state department of public welfare and the Waukegan *News-Sun* are cooperating in an experimental program, which opened on January 13, to determine the public's reaction to education in mental hygiene and allied subjects. Once a week a group of speakers is provided by the state department of public welfare at no charge to the community; the *News-Sun* arranges for the use of a local theater, and the lectures are designed to educate the public in the prevention of mental disease. A question and answer period concludes each session. The program, offered under the name of the Human Relations Institute, has the approval of the Lake County Medical Society. More than eighteen hundred persons attended the last session in January.

Chicago

Drs. Heyd and Ivy to Address Medical Society.—Dr. Charles Gordon Heyd, New York, formerly President of the American Medical Association, will address the Chicago Medical Society, at the Chicago Woman's Club, February 18, on "A Consideration of the Hepatorenal Syndrome" and Dr. Andrew C. Ivy, Nathan Smith Davis professor of physiology, Northwestern University Medical School, "Rationale of Bile Salt Therapy."

Annual Meeting of Heart Association.—The Chicago Heart Association will hold its annual meeting at the Chicago Woman's Club, February 16, with Dr. Sidney Strauss presiding. Other speakers on the program will be Mayor Edward J. Kelly and Dr. Morris Fishbein, Editor of *THE JOURNAL*. Brig. Gen. Lewis B. Hershey, director of the Selective Service System, Washington, D. C., will also speak on "The Medical Profession and Total War."

Physician Must Serve Sentence on Lottery Charge.—The Chicago *Sun* reported that Dr. Frank Deacon, physician at a CCC camp in East Tawas, Mich., must serve a sentence of a year and a day in a federal penitentiary, according to the verdict, December 23, of the First United States Circuit Court of Appeals in Boston. This verdict upheld Dr. Deacon's conviction in the United States District Court in Boston in June 1940, when he was found guilty of charges of conspiracy to transport lottery tickets interstate and cause them to be taken into Massachusetts, it was stated. Evidence showed that a million tickets, to sell at 50 cents each, had been printed monthly and that four prizes of \$20,000 each were offered to the winners. The tickets were issued as "Will Rogers Memorial Hospital Charity Bonds." Dr. Deacon was said to be one of a group of twelve men and two women involved in the lottery ring which had been using the now defunct Will Rogers Memorial Hospital, 6970 North Clark Street, as a basis for their scheme. Altogether seventy-one men and three women were indicted by a federal grand jury. The physician was the only one who elected to stand trial. It was reported that the others pleaded guilty. Dr. Deacon once owned the Jackson Park Hospital. He graduated at the College of Physicians and Surgeons of Chicago in 1904 and was licensed to practice in Illinois the same year.

MICHIGAN

Pharmacist Honored.—The Michigan Branch of the American Pharmaceutical Association gave a banquet in honor of Leonard A. Seltzer, Sc.D., December 29, in Detroit. Dr. Seltzer is an associate member of the Wayne County Medical Society. Guest speakers at the dinner included Dr. Clarence E. Simpson, president of the county medical society, and E. Fullerton Cook, Pharm.M., of the Philadelphia College of Pharmacy and Science.

Professional Liaison Committee.—A Professional Liaison Committee representing the dental, pharmaceutical and medical professions, authorized by the 1941 house of delegates of the Michigan State Medical Society, has been formed as follows: representing the state dental society, C. H. Jamieson, D.D.S., Detroit; Harry F. Parks, D.D.S., Jackson, and F. D. Ostrander, D.D.S., Ann Arbor; representing the Michigan State Pharmaceutical Association, Jack H. Webster, Detroit; Bernard A. Bialk, Detroit, and C. B. Campbell, Jackson; representing the state medical society, Drs. Allan W. McDonald, Detroit; Harrison S. Collisi, Grand Rapids, and Fred R. Reed, Three Rivers.

MINNESOTA

The Bell Lecture.—William H. Feldman, D.V.M., Rochester, delivered the annual John W. Bell Lecture before the Hennepin County Medical Society, Minneapolis, February 2. His subject was "Chemotherapy of Experimental Tuberculosis."

Chemist Honored.—Ross Aiken Gortner, Ph.D., chief in the division of biochemistry, University of Minnesota, St. Paul, has been announced as the 1942 recipient of the Osborne Medal, presented by the American Association of Cereal Chemists to scientists who have rendered distinguished service in conducting research and training students in cereal chemistry. The medal will be presented at the annual meeting of the association next May. Dr. Gortner has been chief in the division of agricultural biochemistry at Minnesota since 1917, during which time he has trained many students who hold positions of leadership in research. He received his Ph.D. at Columbia University, New York, in 1909, joined the faculty at Minnesota in 1914 and was made full professor and division chief in 1917.

Society News.—Dr. George T. Pack, New York, addressed the Minneapolis Surgical Society in Minneapolis, February 5, on "Cancer of the Stomach."—Dr. Ralph M. Waters, professor of anesthesia, University of Wisconsin Medical School, Madison, delivered a Mayo Foundation lecture, January 22, on "The Evolution of Anesthesia."—Dr. Joseph F. Borg, St. Paul, gave the presidential address before the annual meeting of the Ramsey County Medical Society in St. Paul, January 26, on "Prognosis in Heart Disease: Contributions of the Electrocardiogram."—The Minnesota Pathological Society was addressed in Minneapolis, January 20, by Drs. Philip Hallock and Gerald T. Evans on "Orthostatic Hypotension" and George N. Aagaard Jr., "Transfusion Reactions Due to Rh Factor." All are from Minneapolis.

NEW JERSEY

Portrait of Dr. Haussling.—A portrait of the late Dr. Francis Reynolds Haussling, Newark, was unveiled in the board of trustees room of the Newark Memorial Hospital on Dec. 18, 1941. The picture was the gift of Mr. and Mrs. Jacob L. Newman. Dr. Haussling was at one time president of the Essex County Medical Society and of the Medical Society of New Jersey. At the time of his death, Aug. 4, 1941, he was an attending surgeon at the Newark Memorial Hospital.

NEW YORK

Course in General Medicine.—The state medical society will conduct the following course in general medicine before the Columbia County Medical Society at the Hudson City Hospital, Hudson. The lecturers, all of New York, will be:

- Dr. David D. Moore, Diabetes Mellitus, March 12.
- Dr. James L. Miller, Syphilis, March 26.
- Dr. Paul Reznikoff, The Diagnosis and Treatment of Anemia, April 9.
- Dr. William Goldring, Hypertension and Hypertensive Heart Disease, April 23.
- Dr. Albert Vander Veer, Asthma, May 7.
- Dr. Homer F. Swift, Rheumatic Fever, May 21.
- Dr. John D. Lytle, Nephritis, June 4.

Warning on Theft of Narcotics.—The New York State Department of Health, Albany, announces that additional precautions should be taken by hospital and institution authorities in the protection of stocks of legitimate narcotics in an effort to prevent further robberies committed by addicts and illegal dealers in drugs. The department announces that one man has been arrested who had in his possession two bottles containing two thousand tablets of a narcotic drug. An investigation revealed that these tablets and another bottle of one thousand tablets had been stolen from a hospital in the upstate area.

New York City

The Harvey Lecture.—Roger Adams, Ph.D., professor of organic chemistry and head of the department of chemistry, University of Illinois, Urbana, Ill., will deliver the fifth Harvey Society Lecture at the New York Academy of Medicine, February 19. His subject will be "Marihuana."

Ninety Years of Hospital Service.—With the appointment of a special committee, Mount Sinai Hospital announces a program to observe its completion of ninety years of service. It has planned to sponsor a series of lectures during the year to commemorate the event. Prof. Winifred C. Cullis, in charge of the women's section of the British Library of Information, New York, delivered the first lecture in one series, January 28, on "What British Women Are Doing in the War." A group of lectures will be given on blood chemistry. The speakers will include:

- Dr. Donald D. Van Slyke, Acid Base Balance, February 20.
- Dr. John P. Peters, New Haven, Conn., Serum Proteins in Health and Disease, March 6.
- Dr. Fuller Albright, Boston, Phosphate Metabolism in Dysparathyroidism: Renal Insufficiency, Rickets and Osteomalacia, March 10.
- Dr. Henry L. Jaffe and Aaron Bodansky, Ph.D., Serum Calcium: Clinical and Biochemical Considerations, March 13.
- Dr. Reuben Ottenberg, Blood in Jaundice, April 21.
- Warren M. Speery, Ph.D., The Biochemistry of the Lipoidoses, April 28.

This hospital has always been conducted on a nonsectarian basis. It assumed its present name in 1866, moved to its present location at One Hundredth Street east of Fifth Avenue in 1904 and now occupies eighteen buildings covering about three city blocks and has a capacity of about eight hundred and fifty-six beds.

NORTH CAROLINA

Graduate Courses.—The school of medicine and the extension division of the University of North Carolina, in cooperation with local county medical societies, have arranged for a series of postgraduate courses at Fayetteville, Durham, Raleigh and Kinston. Dr. Marvin P. Rucker, Richmond, Va., opened

the course at Durham, January 14, with a discussion on obstetrics, and Drs. Francis C. Wood and Baldwin H. E. W. Lucke, Philadelphia, conducted a clinical-pathologic conference on January 21. Other speakers in the series include:

- Dr. William D. Stroud, Philadelphia, The Failing Heart of Middle Life, January 28.
- Dr. Harrison F. Flippin, Philadelphia, Use of Sulfonamides in General Practice, February 4.
- Dr. Richard B. Cattell, Boston, Surgery, February 11.
- Dr. Charles F. McKhann, Ann Arbor, Mich., Pediatrics—Advances in the Treatment of Infectious Diseases in Children, February 18.

The course at Fayetteville opened, January 22, with Dr. Walter C. Alvarez, Rochester, Minn., speaking on "Diagnosis and Treatment of Common Diseases of the Gastrointestinal Tract." The rest of the course includes:

- Dr. Stroud, The Failing Heart of Middle Life, January 29.
- Dr. James E. Paullin, Atlanta, Ga., Endocrinology and Metabolism in General Practice, February 5.
- Dr. Custis Lee Hall, Washington, D. C., Orthopedic Problems of the General Practitioner, February 12.
- Dr. McKhann, Advances in the Treatment of Infectious Diseases in Children, February 19.
- Dr. Percy S. Pelouze, Philadelphia, Infectious Diseases of the Genitourinary Tract, February 26.

OHIO

The Hanna Lecture at Western Reserve.—Dr. Eduardo Braun-Menéndez, lecturer in physiology and director of cardiovascular investigations, Faculty of Medical Sciences, University of Buenos Aires, will deliver the forty-seventh Hanna Lecture at the Western Reserve University School of Medicine, Cleveland, February 18. His subject will be "The Humoral Mechanism of Renal Hypertension."

PENNSYLVANIA

Society News.—A symposium on "Medical Aspects of Civilian Defense" was presented by Drs. Howard K. Petry, William Paul Dodds and Samuel B. Fluke, all of Harrisburg, at a recent meeting of the Dauphin County Medical Society in Harrisburg on February 3.—Dr. Thomas Peck Sprunt, Baltimore, will address the Harrisburg Academy of Medicine on "Diseases of the Liver," February 17.—At a meeting of the Washington County Medical Society in Washington, February 1, Dr. John O. Rankin, Wheeling, W. Va., spoke on "Preoperative and Postoperative Care of the Surgical Patient."

Philadelphia

Postgraduate Lectures.—A series of postgraduate lectures was presented in Philadelphia, February 2-5, under the auspices of the American College of Physicians. The speakers included:

- Dr. George Morris Piersol, Medical Emergencies.
- Dr. Hobart A. Reimann, Prophylaxis and Treatment of Virus Diseases.
- Dr. Charles L. Brown, Fatigue.
- Dr. George Harlan Wells, Borderline Metabolic Deficiencies.
- Dr. William D. Stroud, Effort Syndrome.
- Dr. Francis C. Wood, Criteria of Organic Heart Disease in Recruits.
- Dr. Thomas M. McMillan, Forms of Cardiac Derangement.
- Dr. John M. Bachelus, Lieutenant commander, U. S. Navy, Lakehurst, N. J., Cardiovascular Problems in Aviation.
- Dr. Edward A. Strecker, Personality Deviations.
- Dr. Earl D. Bond, Early Signs of Psychoses.
- Dr. George Wilson, Traumatic Neuroses.
- Dr. Baldwin L. Keyes, Malingering.
- Dr. Harrison F. Flippin, Pharmacology and Toxicology.
- Dr. John S. Lockwood, Surgical Infections.
- Dr. John A. Kolmer, Medical Infections.
- Dr. Charles A. W. Uhle, Urinary Tract Infections.

On Friday, February 2, the day following the completion of the course, the fourth annual round-up or regional meeting of members of the college from Eastern Pennsylvania, Delaware, and Southern New Jersey was held.

SOUTH CAROLINA

Personal.—Dr. John W. Corbett, Camden, has been chosen the first honorary member of the South Carolina Tuberculosis Association.—Dr. John H. Mathias, Lexington, has been appointed chief of emergency medical service for Lexington County.

Hospital News.—Approval has been given to construction of a fourth story addition to the St. Francis Xavier Infirmary, Charleston, as a defense public works project. A federal grant of \$70,000 will defray part of the expenses. The improvement will make seventy beds available at the hospital.

Society News.—Dr. Julian M. Ruffin, Durham, N. C., discussed "Diagnosis and Treatment of Ulcerative Diseases of the Colon" before the Greenville County Medical Society recently.—The Columbia Medical Society was addressed in Columbia, January 12, by Drs. Charles G. Spivey, Columbia, on "Effect of Pregnancy Urine on Certain Hypopituitary Conditions," and Samuel W. Becker, Chicago, "Allergic Aspects of Dermatology."

TEXAS

Changes in Health Officers.—Dr. Seborn C. Richardson, Bryan, has been named health officer of Bryan.—Dr. Lorence W. Feller, Fredericksburg, has been named health officer of Gillespie County to succeed the late Dr. Joseph E. Peden, Fredericksburg.

Public Health Election.—Dr. Horace E. Duncan, Dallas, health officer of Dallas County, was chosen president-elect of the Texas Public Health Association at its recent annual meeting in Corpus Christi, and Dr. Clarence Burke Brewster, Fort Worth, now on active duty in the medical corps of the U. S. Army, acceded to the presidency. Dr. Harold A. Wood, Austin, director of the Austin-Travis County health unit, and Miss Katherine King Baker, R.N., were chosen vice presidents. Alan C. Love, Austin, sanitary engineer of the Austin-Travis health unit, was reelected secretary-treasurer.

Changes in the Faculty at Texas.—Dr. Jarrett E. Williams, formerly assistant dean, Medical Branch of the University of Texas, Galveston, has been appointed associate dean and general superintendent of the associated hospitals. Dr. William S. Wallace, assistant professor of radiology, has been named assistant dean. A number of new departments have been formed at the medical school, including anesthesiology, biophysics, dentistry and stomatology, which does not deal with the mechanics of dentistry but rather with the broad relationship between medicine and dentistry. Departments of legal and cultural medicine have also been added and one on military medicine, which is oriented with aviation medicine to cover tropical medicine but which is not related to military science and tactics. The department of preventive medicine and public health has initiated a program in tropical medicine and diseases endemic in the Southwest and Old Mexico.

WASHINGTON

Hospital News.—A federal grant of \$476,000 has been given to Bremerton for a new hospital with a capacity of about one hundred and sixty beds.—A new wing will be added to the United States Naval Hospital, Bremerton, at a cost of about \$151,000.

Annual Meeting of Seattle Surgeons.—The Seattle Surgical Society held its annual meeting at King County Hospital, Seattle, January 23-24. In addition to papers by local speakers, the program included symposiums on infection, the use of blood, plasma and fluids, head and neck injuries and gynecologic relaxations. The guest speaker at the meeting was Dr. Frank R. Menne, professor of pathology and head of the department, University of Oregon Medical School, Portland, who participated in the general program and delivered the banquet address on "Lymphosarcoma of Small Intestine with Report of Two Cases Receiving Surgical Intervention."

WISCONSIN

State Health Board Reelected.—At a recent meeting, the state board of health reelected all its 1941 officers. Included are Drs. William W. Kelly, Green Bay, president; Stephen Cabana, Milwaukee, vice president, and Cornelius A. Harper, Madison, secretary and state health officer.

Dr. SeEVERS Goes to Michigan.—Dr. Maurice H. SeEVERS, associate professor of pharmacology, University of Wisconsin Medical School, Madison, has been appointed professor of pharmacology and chairman of the department at the University of Michigan Medical School, Ann Arbor, effective February 1. Dr. SeEVERS graduated at Rush Medical College, Chicago, in 1932.

The First Helmholtz Lecture.—Dr. Anton J. Carlson, Frank P. Hixon distinguished service professor emeritus of physiology, University of Chicago School of Medicine, Chicago, delivered the first annual A. C. Helmholtz Lecture, January 16, under the auspices of the University of Wisconsin Medical Society, Madison. His subject was "Some Unknown Problems in the Physiological Pathology of Aging."

Hospital Association Elects Officers.—The Wisconsin Hospital Association reelected its officers and directors at the January conference in Milwaukee with the exception of Dr. Robin C. Buerki, who in September 1941 became director of hospitals at the University of Pennsylvania and dean of the University of Pennsylvania Graduate School of Medicine, Philadelphia. Dr. Buerki was formerly executive secretary of the University of Wisconsin Medical School and superintendent of the State of Wisconsin General Hospital and the Wisconsin Orthopedic Hospital for Children, Madison. Dr. Harold M. Coon, superintendent of Wisconsin General Hospital, was chosen to replace Dr. Buerki on the association's board of directors. Dr. Edward T. Thompson, medical superintendent, Mount Sinai Hospital, Milwaukee, is secretary-treasurer.

GENERAL

Grants for Research in Poliomyelitis.—The semiannual meeting of the medical committees of the National Foundation for Infantile Paralysis will be held in New York, May 7-8. At this session all grants for research will again be considered. Applications should be filed with the foundation at 120 Broadway, New York, by March 1.

Dates Changed for College of Surgeons Meeting.—Because of the war, the thirty-second annual Clinical Congress of the American College of Surgeons will be held in Chicago, October 19-23, instead of in Los Angeles as originally planned. Headquarters will be at the Stevens Hotel. The twenty-fifth annual hospital standardization conference sponsored by the college will be held simultaneously. The programs of both meetings will be based chiefly on wartime activities as they affect surgeons and hospital personnel in military and civilian service.

Contest on Safety.—The American Museum of Safety announces a contest in an effort to strengthen the country's accident prevention program and perhaps obtain new ideas that will help promote safety and conserve man power for U. S. defense activities. Entries must reach the American Museum of Safety, Room 733, 60 East Forty-Second Street, New York, before midnight February 28. The subject for the contest is "A Plan of Action to Combat the Rising Tide of Accidents in the Present Emergency." Dr. Donald B. Armstrong, New York, is president of the American Museum of Safety and chairman of the Seamen Award Committee, which sponsors the contest.

Holiday Accidents.—According to a survey by the Associated Press, a total of two hundred and sixty-five persons died over the New Year's holiday in automobile accidents, drownings, falls, shootings and by other violent means. Automobile accidents accounted for one hundred and seventy-one of the total. A similar survey showed a national total of four hundred and thirty-one for the Christmas holiday, of which three hundred and thirty-four deaths were in traffic. Ohio recorded the largest New Year's state total of twenty-six deaths, twenty-two of which were in traffic accidents. Illinois' total was twenty-four and New York's twenty-one.

Annual Report of Plotz Foundation.—The Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation in its eighteenth annual report covering 1941 announced that sixty-seven applications for grants were received by the trustees, forty-nine of which came from seven different countries in Europe, South America and Central America. In the year just ended thirty-five grants were approved, one of these being a continued annual grant. In its eighteen years the foundation has made four hundred and twenty-nine grants, which have been distributed to investigators in Arabia, Argentina, Austria, Belgium, Brazil, Canada, Chile, China, Czechoslovakia, Denmark, Egypt, Estonia, Finland, France, Germany, Great Britain, Greece, Hungary, India, Iraq, Italy, Latvia, Lebanon, the Netherlands, North Africa, Norway, Palestine, Peru, Poland, Portugal, Rumania, South Africa, Sweden, Switzerland, Syria, Venezuela, Yugoslavia and the United States. The grants have assisted specific studies in a broad range of medical research.

Syphilis Test Required of Employees.—A recently completed survey shows that more than half of the largest industrial plants in the country are including a routine blood test for syphilis in employee physical examinations, according to the American Social Hygiene Association. More than two hundred large plants in forty-three states answered questionnaires sent out by the association. These plants represent many types of industry and have at least one thousand employees. Two thirds of the companies requiring these tests maintain the policy of accepting infected applicants if they are not infectious, are not disabled and will take treatment. The association states that this policy is even more liberally interpreted for infected workers already employed, three fourths of the companies retaining their employees with the usual provision that they are not to work while infectious and must take adequate treatment. The association believes this a major public health contribution because such measures insure employee confidence and aid case holding by assuring workers that they will not lose their jobs provided they take treatment.

Handicapped Employees Useful.—A study of the experience of sixty-eight industrial companies with handicapped employees reveals that careful selection procedures and placement have been uniformly favorable. According to the Conference Board, New York, nearly one third of these companies employ illiterates, while one fourth employ ex-convicts and workers with physical defects. One company reported that it

had about eighteen thousand physically defective persons on the payroll. Another said that persons who have defective hearing are often superior for inspection work. The survey showed that among employers the principal obstacles to the employment of ex-convicts are the belief that most ex-convicts do not desire to rehabilitate themselves, the practice of hiring only those persons who can be promoted to positions of responsibility, the belief that ex-convicts cannot qualify and the fear that ex-convicts would be objectionable to fellow employees. The survey was designed to show that the estimated 6,000,000 adults in the United States who are handicapped by lack of education, physical defects or criminal records may with careful planning be put to gainful employment.

Physicians Swindled.—A physician in California writes that a man has been calling on physicians in California using the approach that he has a "pain around the heart" and after the visit is concluded he presents a check for more than the amount of service. The man has a mitral murmur, and the unsuspecting physician is apt to make an examination and prescribe some sort of treatment. The man has used the name John Larabee, 2021 Hearst Street, Berkeley, Calif. There is no such address. He states he is 52 years old and a radio operator. The California physician sends the following description: He is 5 feet 10½ inches tall and weighs 152 pounds; his chest measurements are 34 to 39 inches; waist, 32½ inches; patellar reflexes are exaggerated; pupil reflexes, normal; pulse 100, temperature 98, blood pressure 150/80; heart position normal, mitral systolic murmur transmitted to the anterior maxillary line; lungs normal; extremities normal. He has impacted cerumen in both ears and has pyorrhea of all his teeth. In some cases the checks have been made out to J. Larabee and signed "Howard E. Bliss." Across the face of the check is written "Compilation" with some number after it like 18 or 200; in the corner of the check it is marked "Wages." The checks are all numbered 172, irrespective of the bank they are on.

LATIN AMERICA

Personal.—Dr. Luther Vargas, eldest son of President Getulio Vargas of Brazil and chief surgeon of the orthopedic section of Centro Medico Pedagogico Oswaldo Cruz, Rio de Janeiro, has arrived in New York, where he will start a six months study tour of orthopedic clinics in the United States, the *New York Times* reported February 3.

Congress of Tuberculosis.—The sixth Pan American Congress of Tuberculosis will be held in Havana, Cuba, in October 1943. Officers include Drs. Juan J. Castillo, Havana, and Héctor Madariaga, Havana, president and secretary, respectively. Drs. G. Araújo Alfaro, Buenos Aires, Argentina, Clemente Ferreira, São Paulo, Brazil, and John B. Morelli, Montevideo, Uruguay, have been named honorary presidents.

Institute of Hygiene in Ecuador.—A National Institute of Hygiene has been created at Guayaquil, Ecuador; it will be housed in a new building already under construction. The International Health Division of the Rockefeller Foundation, New York, and the government of Ecuador are financing the project as well as sharing the maintenance for a five year period, after which time it is expected that the Ecuadorian government will assume complete responsibility. There will be installed in the new building the laboratories of bacteriology, chemistry, medical researches, preparation of anti-smallpox vaccine, bacterial vaccines, anatoxins, BCG laboratory, special laboratories for epidemics and yellow fever and the like, and in future the preparation of therapeutic serums. It is also planned to have departments for general services to the public.

CORRECTION

Stipends for Young South American Graduates.—In the Buenos Aires letter in *THE JOURNAL*, Nov. 29, 1941, page 1906, the correspondent stated that the Pan American Sanitary Bureau, cooperating with the Rockefeller Foundation, had provided thirty-five stipends to enable young South American graduates to be trained in hospitals in the United States and that seven of these were to be "distributed by Prof. B. A. Houssay." To clarify his participation in this matter, Professor Houssay writes as follows:

The Pan American Sanitary Bureau, in connection with the coordinator of Cultural and Commercial Relations between the American Republics, has provided thirty-five stipends to be distributed in South America, seven of which were planned for Argentina to enable young graduates to be trained in the best hospital service of the United States.

Dr. Felix R. Brunot, representative of the Pan American Sanitary Bureau, visited Buenos Aires and received the applica-

tions of seventeen candidates, which were sent to the United States, where selections should be made.

Designations came from Washington and seven applicants of our country were appointed: Drs. Pedro O. Bolo, Raul Alcayaga, Luis Delfor Podesta, Emilio Araya and Jose Abel Landa from Buenos Aires, and Drs. Mario Besso Pianetto and Alfredo F. J. Cesanelli, from Rosario.

The participation of Prof. B. A. Houssay in this matter was limited, namely, to receive applications and deliver them to Dr. Brunot, on his request. He had no intervention at all in the selection of the candidates.

Government Services

Federal Grants to Assist Hospital Expansion

Announcement is made of a series of Defense Public Works projects which have been approved under the Lanham Community Facilities Act. One unit will be constructed in Charleston, S. C., at an estimated cost of \$675,000 with the capacity of one hundred and forty beds. A one story health center building will be erected in Hattiesburg, Miss., at an estimated cost of \$22,000. The new unit will house the Forrest County Health Department. The Warren A. Candler Hospital, Savannah, Ga., will add a new twenty-five bed addition with equipment. The estimated cost is \$93,398. A one story health center building will be erected in Starke, Fla., at an estimated cost of \$33,000. These projects have been approved to expand local facilities, which have been found inadequate with the increased defense activities.

New Commission to Study Vital Statistics

A national commission on vital records has been created as a special committee of the Health and Medical Committee of the Office of Defense Health and Welfare Services. The new commission was formed at the request of the Association of State Health Executives and the American Association of Registration Executives. Lowell J. Reed, Ph.D., professor of biostatistics and dean of the Johns Hopkins University School of Hygiene and Public Health, Baltimore, has been appointed chairman. The Health and Medical Committee decided to create the commission after representatives of the army, state registrars, state health officers, the Bureau of the Census and the U. S. Public Health Service had "described the difficulties encountered by state offices in trying to maintain efficient service to the public in the face of an overwhelming increase in demands for proof of citizenship." First attention of the new committee will be given to the problem of delayed registration of births.

Major Armstrong Awarded Medal

Major Harry G. Armstrong, U. S. Army Medical Corps, in charge of research at the School of Aviation Medicine, Randolph Field, Texas, has been named to receive the John Jeffries Award given by the Institute of the Aeronautical Sciences for his contributions to the health and efficiency of military and civil aircraft pilots. The award is named after John Jeffries, a Boston physician, who was the first American to make scientific observations from the air. Major Armstrong graduated at the University of Louisville School of Medicine in 1925. He graduated at the Army Medical School, the Army Medical Field Service School and the Army School of Aviation Medicine. According to an announcement, he established the Aero Medical Research Laboratory of the Army Air Corps at Wright Field, Dayton, Ohio, in 1934, serving as director until his assignment to Randolph Field. He was one of the first to describe accurately some specific medical results of flying, such as aeroneurosis, a kind of mental and physical fatigue experienced by fliers under certain conditions; aeritis, an effect of high altitude and acrobatic flying on the human middle ear, and aeroembolism, a reaction similar to the "bends" suffered by deep sea divers, which affects pilots who climb to high altitudes too rapidly and without proper safeguards. Major Armstrong has done much to stimulate further research in the medical aspects of aviation and has led to the development of oxygen supply and pressurizing apparatus and other precautionary procedures for safeguarding pilots against the physical effects of military flying. His volume on "Principles and Practice of Aviation Medicine" is the most complete textbook yet published on the subject.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 27, 1941.

Wartime Prescribing: The National War Formulary

All the normal activities of the country have to be subordinated to the war effort. In previous letters, changes with regard to drugs, such as extending the cultivation of medicinal herbs, formerly largely imported (*THE JOURNAL*, Sept. 13, 1941, p. 948), have been announced. The whole problem of drugs has been systematically dealt with by a committee appointed by the minister of health, which has compiled the National War Formulary. For prescribing under the national health insurance act this replaces the previous national formulary. Since the 1st of December it has not been considered advisable to prescribe any preparation by title only unless its formula is contained in the National War Formulary, the British Pharmacopoeia or the British Pharmaceutical Code. Under the heading of "Wartime Prescribing" the new Formulary describes, in the interests of economy, some general limitations. Agar should be reserved for bacteriologic use. The prescribing of cinchona as a bitter is discouraged; quinine should be reserved for the treatment of malaria. Digitalis is best administered in one-half and 1 grain tablets of the powdered leaf. The liquid extract of ergot is not an economical preparation; the drug is best administered in tablet form. The vitaminized oil of the British Pharmacopoeia has the same vitamin content as cod liver oil and in most cases is a satisfactory alternative. Economy in alcohol is essential; alternatives are suggested for preserving surgical instruments from rust and for surgical and industrial methylated spirit used to prevent bedsores. Liquid petrolatum must be prescribed with regard for economy; when oral administration is considered necessary a 25 per cent emulsion should be used, and even this sparingly. Under a defense regulation liver extracts are controlled; they must be administered only in pernicious or other megalocytic anemia and then only by injection. Malt extract and preparations containing it should be prescribed only for children and tuberculous patients. Phosphorus is wanted for munitions. Therefore phosphoric acid has been replaced by hydrochloric acid, hypophosphites and glycerophosphates have been excluded, and sodium acid phosphate remains for use only in association with methenamine. Potassium salts should be prescribed only when the corresponding sodium salts are not satisfactory. As this holds in the case of potassium chlorate and acetate, they have been retained.

Prescribers are asked not to order confections and lozenges, which require sugar. Dextrose is rarely necessary except for intravenous and rectal administration. Sulfanilamide, sulfapyridine and sulfathiazole are included in the new formulary, but sulfanilamide is declared to be the most generally useful and should be prescribed unless there are specific indications for either of the others. Economy is enjoined in the use of salicylic acid, salicylates, mercury and its compounds, scopolamine and atropine. The use of distilled water should be restricted to applications for the eye and those which, in the opinion of the pharmacist, would be undesirably altered if ordinary potable water should be used. Proprietary preparations of foreign origin should be avoided; in any case many of them are unobtainable.

One difference in the new formulary is reduction of glycerin in the making of preparations. Certain capsules, such as those of ergot, oil of santal and preparations of iron, are omitted. Tablets and pills are declared to be generally preferable to capsules. But capsules of vitamins A and D and of halibut liver oil have been added. Four flavoring and sweetening emulsions—*aniseed*, *aniseed with peppermint*, *chloroform* and *peppermint*

alone—replace alcoholic preparations. For intrauterine use a solution containing 25 per cent of glycerin and 10 per cent of sodium chloride is introduced in place of pure glycerin.

In the mixtures quassia replaces gentian, and sodium sulfate replaces magnesium sulfate. Alcohol is reduced everywhere and glycerin is excluded; hydrochloric acid replaces phosphoric acid; extract of licorice for sweetening is removed or reduced. Bismuth mixture is entirely discouraged, and mixtures containing magnesium trisilicate and carbonate or kaolin replace it.

It should be noted that what is laid down in the National War Formulary is advisory, not compulsory. The physician can still order what he thinks best for his patient, but he is subject to the limitation that certain drugs and preparations are no longer obtainable. Further, the panel physician, prescribing under the national insurance act, has had his formulary altered. If not satisfied with a prescription in the new formulary, he can prescribe according to the old one, but instead of a ready made formula he will have the inconvenience of writing the prescription in full.

International Hospital Collaboration

The king of Norway, the grand duchess of Luxemburg, Dr. Běněš, lately president of Czechoslovakia, the prime minister of the Netherlands, the Belgian ambassador, the ministers of Norway, Venezuela and Colombia, representatives of Poland, Yugoslavia, Greece, Palestine, Iraq, Egypt, Abyssinia, India and China and the British minister of health were present at a conference held in London to consider the position of hospitals the world over when peace comes. The conference was summoned by the United Kingdom Council of the International Hospital Association. Prof. A. T. Jurasz, dean of the Polish Faculty of Medicine in the University of Edinburgh, opened a debate on the collaboration which must follow the war among all nations prepared to work together on a basis of honesty and friendliness. Some nations would have to amend the condition of their minds before they could be accepted. He suggested a greater exchange of personnel, both lay and medical, a six months residence in the larger hospitals for graduates of different countries on a principle of international exchange, an interchange of specialists and an extension of postgraduate teaching. Professor Locwy of Czechoslovakia suggested a "health union" among European countries on the basis of the curative resources of each country, such as mountain sunshine or medicinal springs, and the distribution of patients without regard to national boundaries. Dr. E. J. Bigwood, chairman of the Belgian commission for the study of postwar conditions, stated that governments of the allied countries now in London had already considered a plan for immediate relief after the war and for long term development.

HOSPITALS IN ENGLISH SPEAKING COUNTRIES

Mr. McAdam Eccles (surgeon), chairman of the United Kingdom Council, who presided, opened a discussion on the special needs of English speaking countries. He suggested that the total number of beds required in any area and the expected number of outpatients should be computed and the annual cost calculated and announced to the local community, who, he did not doubt, would provide it voluntarily. Mr. H. S. Souttar (surgeon) referred to the sweeping away of the divisions between voluntary (supported by voluntary subscriptions) and municipal hospitals. Mr. Ernest Brown, minister of health, mentioned the close relation between Britain and the United States in connection with the Emergency Hospital Service (established for the care of civilians injured in the war). The United States not only had given material help but had lent medical and nursing personnel. The Emergency Hospital Service had assumed a shape which had made possible adaptation to war needs of all kinds of existing hospitals and services.

Medical War Relief

In September 1940 a medical war relief fund was established to give temporary assistance to British physicians and their dependents who were in financial straits as a result of war conditions. An appeal for funds was made to British physicians and medical organizations with the result that \$170,000 was raised in the first year. In addition to this sum \$22,500 has been received from the British Medical Association of Australia, \$1,500 from the Malaya branch of the association and \$1,750 from British Columbia. The fund has to provide not only for cases arising out of regular warfare but also for those arising from the indiscriminate attacks from the air, on our cities and towns.

A report of the first year's work of the fund shows the kind of tragedies in which physicians and their families have been involved. In 5 cases the beneficiaries of the fund are dependents of physicians killed on active service with our forces. An equal number of awards have been made in cases of four physicians killed and one disabled while engaged in civil defense duties or ordinary civil practice. Sixteen physicians helped were in difficulties resulting from the bombing of their homes or offices, with destruction or damage to their cars, furniture, instruments or other possessions. In 7 cases assistance was given to physicians temporarily in difficulty owing to loss of patients through evacuation and in 8 cases to physicians in financial straits caused by reduction in income as a result of joining the fighting services or who required help in reestablishing themselves in their practices after relinquishing their commissions on grounds of ill health. Grants to widows and other dependents of physicians have always taken the form of gifts, and in many other cases this seemed to be the only appropriate form of help. Those whose difficulties seemed likely to be only temporary requested and received loans.

The distribution committee has worked in cooperation with the Royal Medical Benevolent Fund, which was established a century ago for the relief of distressed physicians and their widows and orphans, for whom it provides annuities in the more urgent cases when the applicant is above the age of 60. This fund, with its long experience, has proved most helpful to the War Relief Fund. When widows with young children have been voted sums toward educational expenses over a period of years the Benevolent Fund, so experienced in such matters, has undertaken the administration with discretion to vary the instalments.

The British Journal of Surgery

Professor Hey Groves has resigned the position of editor of the *British Journal of Surgery*, which he has occupied for twenty-eight years, since the foundation of this periodical. A period of ill health, aggravated by enemy action, is his reason for relinquishing a task performed with high ability. He was one of the founders of the *Journal* and has shown himself a great editor of a journal which worthily represents British surgery all over the world. The project of founding the *Journal* originated in Bristol, the home of Hey Groves. The support of the leading British surgeons was secured, and Moynihan was the first chairman of the editorial committee. Hey Groves is succeeded by C. P. G. Wakeley, surgeon to King's College Hospital.

Anglo-Soviet Medical Relations

An Anglo-Soviet Medical Committee consisting of members of the medical and dental professions and students of these professions, as associate members, has been formed in England with the following objects: 1. To form a liaison between the medical professions of the two countries. 2. To exchange the latest clinical and scientific knowledge. 3. To facilitate visits of medical specialists between the two countries. 4. To give specialist advice on medical aid to the Soviet Union. The mini-

mum subscription for associate members will be \$125. A bulletin will be published from time to time giving reports of the committee's work. The president of the committee is Sir Alfred Webb-Johnson, president of the Royal College of Surgeons.

RIO DE JANEIRO

(From Our Regular Correspondent)

Jan. 5, 1942.

Demographic Census

The last census of Brazil demonstrated that on Sept. 1, 1940 Rio de Janeiro had 1,781,567 inhabitants. The statistics showed a decrease in births in that city. While in the 1921-1930 period the births were 344,921, in the 1931-1940 period only 321,976 births were registered, although there was an increase in the population. The deaths were 248,964 in the first period and 274,223 in the 1931-1940 period. This increase is not in proportion to the growth of the population, showing that there are better conditions of health. In the same periods the marriages numbered 80,545 and 106,112 respectively. These figures demonstrated the tendency of decrease in birth rate, although there

The Most Largely Populated Cities in Brazil

	No. of Inhabitants
Rio de Janeiro	1,781,567
São Paulo	1,308,000
Recife	348,472
Salvador (Baía)	291,000
Porto Alegre	275,739
Belo Horizonte	211,650
Belem (Pará)	208,706
Fortaleza	174,855
Santos	170,000
Niterói	143,004
Curitiba	142,855

has been an increase in the number of marriages. The last demographic census indicated that the most largely populated Brazilian cities are these shown in the table. The population of the capitals of the states was 5,661,091 in 1940, or 13.6 per cent of the population of the whole country. In 1920 this figure was only 2,473,689, or 8.6 per cent of the whole nation. This shows that the people, on the whole, prefer city life to country life.

Brazilian Congress of Surgery

The third Brazilian Congress of Surgery was held at Rio de Janeiro on Nov. 16-22, 1941. Many surgeons came from Argentina, Paraguay, Chile, Uruguay and several Brazilian states. The official papers were read by Profs. Julio Diez of Buenos Aires, Jayme Poggi of Rio de Janeiro and Ottobri Costa of São Paulo on the subject of surgical treatment of pain. Papers were read also by Profs. Manuel Riveros of Asunción, Mota Maia of Rio de Janeiro and Alipio Correia Netto of São Paulo on burns. Profs. Barbosa Vianna of Rio de Janeiro and Edmundo Vasconcellos of São Paulo read papers on amputations from the functional point of view. Many other papers were read before the congress by Brazilian surgeons.

Dr. Raymundo Pires de Albuquerque proposed a new technic for temporary ligation of the appendical stump. Drs. Ney Penteado de Castro and Eurico Branco Riberio were able to show the good results obtained with the alcoholization of the hypogastric plexus as a substitute for the Cotte operation. Dr. Jassy Teixeira advocated extradural anesthesia in thoracic surgery. The problems of hyperthyroidism in pregnant women were discussed by Dr. Mariano de Andrade. Dr. Henrique Smidt spoke about the painless postoperative period, obtained by alcoholization of the mesoappendix.

PARIS

(From Our Regular Correspondent)

Dec. 31, 1941.

The New Law Against Alcoholism

A new law against alcoholism published in the *Journal officiel* of October 8 has been passed in order to lessen the drinking of apéritifs made of distilled alcohol and essences. These apéritifs are being drunk in great quantities especially in the north of France, as against the south of France, where wines predominate.

The toxicity of industrial alcohols has been proved in various experiments by Joffroy, Servaux and Picaud, who set up a table showing an increasing toxicity in the following order: ethyl alcohol, propyl alcohol, butyl alcohol, amyl alcohol. Supposing the height of toxicity to be, for instance, 1 for ethyl alcohol (wine alcohol), it amounts to 3 for butyl alcohol and to 10 for amyl alcohol.

The new law took the place of the one of Aug. 23, 1940, which restricted in France the sale of all apéritifs made of industrial alcohol. Not authorized are apéritifs made of wine containing more than 18 per cent of alcohol or more than $\frac{1}{2}$ grain of an authorized essence in 1 liter. Even the so-called digestifs containing more than $\frac{1}{2}$ grain of essence in 1 liter are forbidden. The board of health can interdict drinks that are considered noxious. The selling of all drinks except wine to persons under age is not allowed. All drinks except wine are to be had only on three days a week. Beverages considered authorized apéritifs and digestifs can be taken on those days only at limited hours. An exception is granted for grog, allowed to be sold from November 1 to April 1 every day at fixed hours. All publicity of apéritifs is forbidden as well as the advertisement of their supposed medical qualities.

The law does not admit the opening of new bars selling apéritifs. But even other bars selling wine or liquors can be admitted only if the authorized quota of one bar for four hundred and fifty inhabitants has not been exceeded. The alcohol problem is economic as well as medical. The alcohol problem is connected with the alimentary difficulties France is suffering nowadays. Intensive discussions are going on in the medical reviews and at the meetings of medical societies. There are physicians requesting the interdiction of all alcohol, even wine, but the latter are in the minority.

Professor Mouriquand, the vitamin specialist, discussed the toxic effect of an excess of wine in a remarkable lecture before the Medical Society of Hospitals in Lyons (Société médicale des hôpitaux de Lyon). The intoxication due to alcohol, as apéritifs and liqueurs, affects especially the assimilation of vitamins soluble in water (vitamin B₂ and vitamin C). Excess of wine, which has also a toxic effect, causes after some time a cirrhosis disturbing the assimilation of the oil soluble vitamins A, K and E, but this disturbance of the liver function can also hinder the assimilation of the other vitamins (B₁ and B₂). Our actual deficiency of vitamins in food requires the suppression of all agents disturbing the assimilation of vitamins.

Some time ago the review *Concours médical* summarized the principal requests of French physicians in the following way: (1) to diminish the number of bars, (2) to regulate the selling of wine by means of an individual ration card (0.5 liter for a person, 1 liter for workmen), (3) to allow the observation and hospitalization of drunkards. The Academy of Medicine has proposed similar requests recently.

Typhoparatyphoid, Diphtheritic and Tetanus Vaccine

At a meeting of the Academy of Medicine, Professor Ramon, scientific director of the Pasteur Institute in Paris, reported a new formula for the associated typhoparatyphoid, diphtheritic and tetanus vaccine. The advantage of the new vaccine is that

it causes fewer severe reactions. Two modifications have been introduced. First, formaldehyde has been applied for the preparation of the typhoid and paratyphoid vaccine. Second, the number of typhoid and paratyphoid germs has been diminished. If one heats the combined vaccine to 54 C., the formaldehyde contained in the mixture seems to cause a modifying effect on the typhoid germ.

The number of typhoid and paratyphoid bacilli in 1 cc. of the new vaccine amounts to 0.7 billion Eberth's bacilli, 0.3 billion paratyphoid A, 0.5 billion paratyphoid B and 13 to 14 units each of the two anatoxins; before it amounted to 1,050 billion Eberth's bacilli, 0.7-billion paratyphoid A and 0.7 billion paratyphoid B in 1 cc. By inoculation of the new vaccine, administering in three times in intervals of fifteen days each 1 cc., 2 cc. and 2 cc., 7.5 billion germs and 65-70 units each of tetanus and diphtheria anatoxins are introduced into the body, instead of the old formula of 12 billion of germs and 70-75 units of each anatoxin.

A child used to get in four injections (0.5 cc., 1 cc., 1.5 cc. and 1.5 cc.), altogether 11 billion germs and 60 to 65 units. By means of the new vaccine a child at the age of 3 to 7 years gets in three inoculations (0.5 cc., 1 cc., 1.5 cc.) with intervals of fifteen days each only 4.5 billion bacilli. A child over 7 years gets 7.5 billion, the number of germs a grown up person should get.

Several thousand inoculations of school children have been performed without any noxious sequels. Thousands of young people have also been vaccinated. The local reaction is inconsiderable and the general reaction seldom causes the temperature to rise above 39 C. (102.2 F.). The maximal temperature is reached six to twelve hours after vaccination, and it usually recedes in twenty-four hours.

According to the serologic tests among vaccinated persons the new vaccine has the same immunization qualities as the vaccine formerly used. Inoculation with this vaccine is obligatory for certain groups of the population.

Death of Prof. Francis Rathery

Professor Rathery, who died some months ago at the age of 64, was well known in France through his most remarkable researches on kidney physiology and pathology, realized partly with his master Castaigne. His contributions to the treatment of metabolic diseases such as rheumatism, gout and especially diabetes and to the effect of insulin gained renown in France and all other countries. He displayed profound knowledge of metabolic diseases. In 1936 he lectured on the spa treatment of diabetes at the International Congress of Medical Hydrology, Climatology and Geology at Belgrade. In 1926 he was appointed professor of pathology at the Faculty of Medicine of Paris, succeeding Professor Roger. He became a member of the Academy of Medicine in 1932 and was appointed vice president of the Biologic Society in 1937. He was general secretary and later on president of the Association of Physicians in Paris.

Marriages

DAVID JULIAN SOBIN, Carsonville, Mich., to Miss Florence Markle of Winnipeg, Man., Canada, in Detroit in September 1941.

EMERSON LOUIS MEYER to Miss Addie Marie Grant, both of Healdsburg, Calif., Aug. 31, 1941.

JOHN F. LUBBEN JR., Dallas, Texas, to Miss Virginia Breeding in Houston, Nov. 22, 1941.

LOUIS D. BOSHES to Miss Rhea Amber, both of Chicago, January 4.

FRANK A. CALDERONE to DR. MARY STEICHEN, both of New York, Nov. 26, 1941.

Deaths

Isadore Julius Wolf, Kansas City, Mo., Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria Germany, 1887, at one time lecturer and professor of medicine at the University Medical College, Kansas City, professor emeritus of medicine at the University of Kansas School of Medicine, Kansas City, Kan., member of the Missouri State Medical Association on the staff of the St. Joseph's Hospital, president of the staff of the Menorah Hospital, 1936-1937, consulting physician, Kansas City General Hospital, author of "A Family Doctor's Notebook, 1940 aged 77, died Dec 17, 1941, of cerebral hemorrhage.

John T. Farrell @ West Warwick R. I., Jefferson Medical College of Philadelphia 1886, an Affiliate Fellow of the American Medical Association president of the Providence Medical Association, 1913-1914, past president of the New England Roentgen Ray Society formerly on the staff of St. Joseph's Hospital Providence, was a member of the consulting staff of the Charles V. Chapin Hospital Providence, aged 83, died Oct. 13, 1941 of nephritis uremia and arteriosclerosis.

Arthur Hutchinson Terry, Patchogue N. Y. College of Physicians and Surgeons, medical department of Columbia College, New York, 1882, member of the Medical Society of the State of New York, past president of the Suffolk County Medical Society, the Associated Physicians of Long Island and the Southside Long Island Clinical Society, formerly member of the board of education, aged 84, died Dec. 26, 1941, of lobar pneumonia.

Michael A. Dailey @ Colonel, M. C., U. S. Army Baltimore, Harvard Medical School, Boston, 1907, was commissioned a first lieutenant in the medical corps of the United States Army in 1912 was promoted through the various grades to that of colonel in 1932, served during the World War fellow of the American College of Physicians, aged 59, died Oct. 27, 1941 of injuries received in an automobile accident.

Joseph Dempsey Thompson, Port Arthur, Texas, Memphis (Tenn.) Hospital Medical College, 1906, member of the State Medical Association of Texas, past president of the Caddo Parish (La.) Medical Society, formerly a member of the United States Public Health Service, aged 62, at one time on the staff of St. Mary's Hospital, where he died Dec. 25, 1941, of hypertension and cerebral hemorrhage.

Charles Van Wood, Cedartown, Ga. University of Tennessee Medical Department, Nashville 1896, member of the Medical Association of Georgia, past president and vice president of the Polk County Medical Society, on the staffs of the Hall-Chaudron Hospital and the Cedartown Hospital aged 66, died Dec. 23, 1941 of carcinoma of the stomach.

Merle Dunning Pierson, Detroit, University of Michigan Medical School, Ann Arbor, 1922, member of the American Academy of Pediatrics, aged 50, on the staff of the Children's Hospital, secretary of the medical executive committee and member of the pediatric staff of the Woman's Hospital where she died, Dec. 20, 1941 of tuberculous meningitis.

John H. Bong, Jasper, Minn., Minneapolis College of Physicians and Surgeons 1897, member of the Minnesota State Medical Association, formerly president of the local board of health, mayor of Jasper, aged 69, died, Dec. 13, 1941, in Pipe stone of cellulitis of the right arm and streptococcal septicemia.

Lawrence Beaucham Owens, Columbia, S. C. Medical College of the State of South Carolina Charleston, 1893, member of the South Carolina Medical Association, mayor of Columbia, on the honorary staff of Columbia Hospital aged 74, died, Dec. 9, 1941, of coronary thrombosis following pneumonia.

Miles J. Lewis, Marion, Ind., Medico Chirurgical College of Philadelphia 1897, member of the Indiana State Medical Association, past president of the Grant County Medical Society, aged 66 on the staff of the Marion General Hospital, where he died, Dec. 31, 1941, of cerebral hemorrhage.

Eugene Graham Mattison, Pasadena Calif., University of Southern California College of Medicine Los Angeles, 1906 fellow of the American College of Surgeons, was on the consulting staff of the Collis P. and Howard Huntington Memorial Hospital, aged 60, died Nov. 30, 1941.

Donald Thomas MacPhail @ New York, Medico Chirurgical College of Philadelphia, 1896, served during the World War, visiting surgeon Manhattan Eye, Ear and Throat Hospital and the New York Eye and Ear Infirmary, aged 70, died Dec. 16, 1941, of coronary occlusion.

Frederic Erskine Montgomery, Forest Hill, N. Y., George Washington University School of Medicine Washington, D. C., 1904, served during the World War, aged 59, died, Dec. 28, 1941, in St. Luke's Convalescent Hospital Greenwich, Conn., of coronary disease.

Charles Wilson Johnson, McLeansboro Ill. Barnes Medical College, St. Louis, 1899, veteran of the Spanish American War, county sheriff, at one time contract surgeon in the U. S. Army, aged 68, died Dec. 23, 1941 in Jefferson Barracks, Mo. of arteriosclerosis.

Eugene Keene Jaudon, Miami Fla., Medical College of the State of South Carolina Charleston 1896, served during the World War, aged 74, died Dec. 19, 1941 in the Veterans Administration Facility Bay Pines, of myocardial insufficiency and coronary arteriosclerosis.

James Cox Markoe, St. Paul, Jefferson Medical College of Philadelphia 1882 member of the Minnesota State Medical Association, past president of the Ramsey County Medical Society, aged 85, died Nov. 28, 1941 of uremia arteriosclerosis and heart disease.

Harry Benjamin Davis @ Kansas City Mo. University of Louisville (Ky.) Medical Department 1908 member of the American Academy of Ophthalmology and Otolaryngology, served during the World War aged 58, died, Nov. 23, 1941 of heart disease.

William Roland Butler, Crystal City Texas University of Arkansas School of Medicine, Little Rock, 1901, member of the State Medical Association of Texas aged 75, died Oct. 21, 1941, of hemiplegia uremia and carbuncle.

Frank Lincoln Tozier, Fairfield Maine University of Vermont College of Medicine, Burlington 1901 member of the Maine Medical Association, aged 72, died Oct. 1, 1941, of diabetes mellitus and gangrene.

Harris Chaim Flinder, Baltimore Russian University of Warsaw Faculty of Medicine 1886 Baltimore University School of Medicine, 1902, aged 75, died Nov. 20, 1941, in the Sinai Hospital of heart block.

Leonidas V. Smith, Floydada Texas Fort Worth School of Medicine Medical Department of Fort Worth University 1906, aged 61, died Oct. 6, 1941 in the Plainview (Texas) Hospital of diabetes mellitus.

C. Frank Hertzog, Olev Pa. Medico Chirurgical College of Philadelphia 1889 member of the Medical Society of the State of Pennsylvania aged 76, died Nov. 4, 1941 of carcinoma of the rectum.

Phonrose Lewis Gardner, Kansas City Mo. University Medical College of Kansas City, 1905 member of the Missouri State Medical Association, aged 61, died Dec. 1, 1941.

John Chiavetta, Phoenix Ariz. Rush Medical College, Chicago 1935 member of the Arizona State Medical Association aged 38, died Oct. 21, 1941 of streptococcal pneumonia.

Charles Byron Porter, Old Town Maine, University of the City of New York Medical Department 1880, aged 86, died Oct. 7, 1941 in Bangor of hypostatic pneumonia.

Emma Caroline Lafontaine, San Francisco, Cooper Medical College San Francisco 1887, member of the California Medical Association aged 77, died Nov. 16, 1941.

James Brown Graff, Worthington Pa., University of Pennsylvania School of Medicine Philadelphia 1910, aged 58, died, Oct. 13, 1941 of chronic myocarditis.

Samuel Brown Gray, Pennsville Pa., Jefferson Medical College of Philadelphia 1909 aged 55, died, Oct. 3, 1941 of cerebral hemorrhage and hypertension.

Victor Percy Fleming, Tujunga Calif., University of Toronto Faculty of Medicine, Toronto Ont. Canada 1916, aged 52, died Nov. 18, 1941.

Thomas Bertram Williams, Glendale Calif., Stanford University School of Medicine, San Francisco 1925, aged 41, died Nov. 28, 1941.

Robert Everett Redmond, Jackson Center, Pa. Menn Medical College Cincinnati 1882, aged 85, died Oct. 14, 1941 of myocarditis.

Clarence V. Ward, Indianapolis Kentucky School of Medicine, Louisville 1900, aged 67, died Nov. 7, 1941, of coronary occlusion.

Don Creed Wills, Arrington Va. Medical College of Virginia Richmond 1918, aged 68, died Nov. 23, 1941 of bronchopneumonia.

Guy McKevitt Johnson @ Los Angeles North Western University Medical School Chicago, 1908, aged 66, died Nov. 15, 1941.

CARE OF AVIATION PERSONNEL

To the Editor:—Referring to the article entitled "A Panoramic Sketch of the United States Army Medical Service Today" by Joseph R. Darnall, M.D., Lieutenant Colonel, M. C., U. S. Army, Washington, D. C., appearing in *THE JOURNAL*, Dec. 20, 1941, I would mention the School of Aviation Medicine located at Randolph Field, Texas, the medical service with the Air Corps, with its group and squadron aid stations, and the Aero-Medical Research Laboratory, Wright Field, Dayton, Ohio. The paramount role that the air forces are now playing in this war should be included in any attempted portrayal of the medical service of the United States Army.

In the last war it was learned that in the selection, maintenance and care of flying personnel the average medical officer is no more professionally equipped to discharge these duties than the average expert chauffeur is to pilot an airplane. It was soon learned that in order to equip a medical officer for his duty as a flight surgeon it was necessary that he have special knowledge of physiology, neurology, psychology, cardiology, ophthalmology, otology and organic chemistry, particularly applicable to aviation medicine. As a result of the investigations carried on and the practical application of the knowledge gained, the U. S. Army Air Corps enjoyed a much smaller mortality rate among fliers toward the end of the war than did our allies, who were slow to follow our example.

After the war and for several years the School for Flight Surgeons was located at Mitchell Field, New York, and then moved to Brooks Field, Texas, where was located our primary flying school. When Randolph Field was opened the school, then known as the School of Aviation Medicine, was moved to this new field—the West Point of the Air.

It has been a constant struggle on the part of a few medical officers to maintain the spark of life in the School of Aviation Medicine over the period of lean and unsympathetic years from the ending of the last war to the present, and it is small wonder that its existence has been overlooked. Our air force was permitted to dwindle to a deplorable state, and the School of Aviation Medicine suffered likewise. It was necessary to rob Air Corps stations of needed personnel in order to maintain a staff of instructors at the school. The general importance of this branch of medicine may be realized by the fact that the Navy detailed medical officers to this school for several years and until they established their own School of Aviation Medicine.

Today the great need for flight surgeons is beginning to be manifested, and tremendous effort is being made, with facilities which are still none too adequate, to train rapidly a sufficient number of flight surgeons to meet our present and future needs.

The special training given medical officers at the School of Aviation Medicine is in the nature of a postgraduate course and stresses the practical application of the various subjects taught there as preventive medicine. That is to say, the flight surgeon applies his knowledge in a practical manner to the preservation of the mental and physical condition of the flying personnel. The flight surgeon is well acquainted with the effects of a lack of oxygen, resulting in "anoxia," the effects of rapid ascent to high altitude, resulting in hematoaeremphysema and the effects of extragravitational forces, resulting in "amaurosis" and syncope. He knows the cause and effect of fatigue in flying personnel and the cause and effect of nervous and mental strain and indoctrinates this personnel in all particulars and practical measures for the prevention of untoward symptoms and consequences. He is trained to detect early symptoms of nervous,

mental or physical fatigue in his flying personnel and to take steps to relieve these conditions before the breaking point is reached.

He knows that the capabilities of the modern military aircraft far exceed the physiologic limits of man and that the efficiency of the airplane is equal only to the efficiency of its operating personnel, and it is his duty to maintain the efficiency of the individual members of his organization's flying personnel, whether they are command pilot, pilot, copilot, navigator, radio operator, gunner, bombardier or observer.

Much of this special knowledge has been gained through the difficult but untiring efforts of the Aero-Medical Research Laboratory located at Wright Field.

Contrary to the common belief that a flight surgeon does nothing but watch his flying personnel and fly about the country on "visits," the fact that a medical officer is rated a flight surgeon does not in any sense relieve him of the routine duties of a medical officer who is not so rated. The duties of a flight surgeon are "additional" duties. It is to be borne in mind that not all the personnel of an air force combat unit is flying personnel. In aerial combat it is not infrequent that crew members are seriously injured but able to return to their home base, where they must be treated in the same manner as casualties occurring on the ground. In air raids on air bases the flight surgeons and their enlisted assistants are apt to be suddenly swamped with large numbers of casualties. Military hygiene and sanitation have the identical standards at Air Corps bases, airdromes and installations, as do posts, camps and stations of other branches and arms of the service.

Flight surgeons are required to fly with their flying personnel in order to observe the psychologic and physical reactions of this personnel in the air and while actually under the stress and strain accompanying the various types of flights and duties performed. Frequently elements of their units will be widely dispersed, and it is necessary to travel from point to point by air to render necessary medical attention and make the necessary sanitary inspections. Frequently it is necessary for a flight surgeon to accompany patients evacuated by air and render necessary treatment en route.

It is necessary for a flight surgeon to understand from actual experience in the air what the problems encountered are and evaluate each individual flying officer and enlisted man's reaction thereto, as it is his duty to recommend the temporary relief from or the return to flying duties of all such personnel, based on their mental and physical fitness.

It may be easily surmised that a medical officer or any one else who has no knowledge of the various duties and problems arising and confronting flying personnel would be extremely presumptuous to recommend relief from or retention to flying of this personnel, which has been specially trained in these duties at tremendous expense to the government. On the other hand, a medical officer who by his training and diligence is enabled to remove from flying, temporarily, an individual who is about to become a total loss, by proper action rehabilitate that individual and finally return him to an extended period of the duty for which he has been trained is not only accomplishing an important economical saving for the government but also actually saving lives. Flight surgeons are indeed cheap insurance when, by their efforts, they may prevent the crash of a single four motor bomber, the loss of which means not only valuable lives from a military standpoint but also hundreds of thousands of dollars in equipment.

At our many training stations where we are training thousands of young men as pilots, the flight surgeon must be on the alert to pick out trainees who are showing symptoms of overstrain, as it is in this category that the first and one of the

greatest stresses is placed on the future flier. With this in mind, it is of paramount importance that those trainees who are unable to withstand completely this stress be eliminated early and before they do irreparable damage to themselves and others.

It appears that we were caught "napping" at Pearl Harbor—unprepared and inadequate at Manila. We are inadequate now in the field of aviation medicine. The awakening to full "air consciousness" of the medical profession is an urgent necessity which must not be ignored.

ALLEN D. TANNEY, M.D., New York.

SPEEDING PRODUCTION OF PHYSICIANS

To the Editor:—I have read your editorial on speeding production of physicians with great interest. I certainly agree with you on the need of thinking through the implications of the accelerated plan. May I submit the following calculations as bearing on the annual production of physicians under the two plans:

Let us assume that the total number of students enrolled in medical schools in this country (N) is approximately four times the number now graduated annually:

$$N = 4 \times 5,300.$$

Under the proposed accelerated plan, N students will be graduated after each three year period, or, in a period of twelve years, a total of $4N$. Under the existing four year plan the total number graduated in the twelve years would be only $3N$. Thus when the whole college-medical school system is geared to the accelerated plan the total annual production of physicians would be increased by $\frac{4N - 3N}{12} = \frac{4 \times 5,300}{12} = 1,767$ physicians

a year. If both colleges and medical schools become geared to the accelerated program, and if the enrolment of colleges and medical schools does not change, the increase will be accomplished without admitting any larger proportion of college graduates to medical schools than at present. If the "speed up" process should be continued long enough, either the secondary schools, the primary schools and eventually the birth rate would have to be geared into the same accelerated pace or a larger proportion than at present of students would have to be admitted to some higher level from some lower level in the educational scheme. However, I trust that the war will be over before it goes this far.

Our own faculty, I may say, has tentatively favored an acceleration plan of completing the course in three years but is still allowing two weeks for vacation at Christmas time and five weeks for vacation in the summer.

STUART MUDD, M.D., Philadelphia.

SUDDEN DEATH IN HEART DISEASE

To the Editor:—Dr. Baer's communication to THE JOURNAL, January 17, commenting on our article "The Sudden Death of Patients with Few Symptoms of Heart Disease" interests us very much because it represents the fairly typical reaction of some physicians when confronted by a proposed therapeutic regimen whose basis is physiologic experimentation. The objections offered to the use of theophylline with ethylene diamine intravenously are: "However, I feel it is not entirely just to develop the (proposed) therapeutic regimen in man"; "There are a number of additional reasons why I think the routine administration of theophylline with ethylene diamine (aminophylline) and atropine is inadvisable"; "I believe a patient with an

acute myocardial infarct should have as little intravenous medication as possible."

These are not very logical objections.

It is recognized by most physicians that a powerful vasodilating drug should be given intravenously with caution to any patient, and particularly when there is known to be a recent myocardial infarction. In the case of theophylline with ethylene diamine this may be accomplished by giving the drug slowly. In our experience no ill effects have occurred in patients or dogs after the use of this drug. Usually only the initial doses are given intravenously; the others are given intramuscularly. The rationale of the therapy—namely, the protection of the uninfarcted myocardium from vasoconstrictor reflexes—requires the administration of the therapeutic agents in a manner that will assure the attainment of the objective. It is also our practice to give coronary vasodilator drugs intramuscularly or orally during the entire period of hospitalization and often for prolonged periods thereafter. Thus late ventricular fibrillation may be less likely to occur.

The concluding paragraph of Dr. Baer's letter represents a misconception of the whole purpose of our paper. He points out, quite correctly, that mortality rates for acute myocardial infarction vary from 8 per cent to 35 per cent and then argues that, since in dogs we reduced the mortality to only 25 per cent, the proposed treatment will not result in much improvement. In untreated dogs, with a complete coronary occlusion and extensive infarction of the left ventricle, the death rate was 75 per cent, and by treatment it was reducible to 25 per cent. To us this means that only one third of the animals destined to die because of myocardial infarction and ventricular fibrillation do so when the reflex mechanisms responsible for death are circumvented. In patients—most of whom have less serious infarctions—a comparable effect would result in a reduction of the mortality rate from 35 per cent to 12 per cent or from 8 per cent to 2.5 per cent, depending on which of Dr. Baer's data one uses. I am not willing to believe that this advantage "would offer little improvement over our present death rate." The experience of the Third Medical service (N. C. Gilbert, M.D., chief) at St. Luke's Hospital, Chicago, with this form of therapy amply justifies the assumptions presented here and will be reported soon.

GEORGE V. LEROY, M.D.

S. SINCLAIR SNIDER, M.D.

Chicago.

TREATMENT OF OSTEOMYELITIS

To the Editor:—The Dec. 13, 1941 issue of THE JOURNAL carries the paper of Drs. Hoyt, Davis and Van Buren in which it is said that I have always advocated some sort of drainage in cases of acute hematogenous osteomyelitis. Yet further along in the paper is a quotation from my writings in which it is specifically stated that such foci of osteomyelitis frequently go on to healing without operation of any kind. I wish to state that the latter statement is the correct point of view.

I should like to emphasize again the more and more frequent possibility of treating this form of osteomyelitis without operation and in the most conservative manner. In previous years this has repeatedly been possible in my experience without chemotherapy, and now with chemotherapy it seems as if this possibility should be accepted as almost a routine response when the condition is seen early; chemotherapy should be properly employed in sufficient dosage and for a sufficient length of time. At last nature is being given the opportunity to do things that operative surgery alone has never been able to do in the past.

A. O. WILENSKY, M.D., New York.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Act: Cancer Allegedly Resulting from Trauma—In the course of her employment in September 1938 Mrs Webb claimed to have been struck on her right breast by a large spool of yarn. The blow caused "a little purple spot" on the breast, and by the time she returned home that evening there was "a little lump" in the bruised spot. However, she suffered no pain and continued to work until the following April, when a "lump" having developed in the breast she consulted her family physician, who made a diagnosis of cancer. She was thereafter confined to bed until her death in February 1940 from cancer. Mrs Webb, so she stated, had never before the date of the alleged industrial accident received any injury to her breast, nor had any one in her family ever had cancer. In November 1939 Dr Laws, who was then in charge of the case following the death of the original family physician, removed her right breast. Mrs Webb instituted suit against her employer in January 1940 under the Tennessee workmen's compensation act, in general ascribing the cancer to the industrial accident. Specifically, she alleged "because of the blow the tissues in her breast had been torn loose and weakened and the blood cells and blood vessels therein had been damaged so that by gradual process which was not detectable, a malignant condition was developing." The trial court dismissed the suit on demurrer but the Supreme Court of Tennessee on appeal reversed the judgment of the trial court and remanded the cause for further proceedings. In the meantime, Mrs Webb had died and the suit was revived in the name of her administratrix, and went on to trial. The trial court found for the employer on the ground that "The proof does not establish as a fact that the deceased died as a result of a cancer caused by her alleged injury. That disease is too common to attribute it to a specific cause on mere speculation." An appeal was then had to the Supreme Court of Tennessee.

The principle complaint of the appellant was that the trial court had erred in holding that the proof adduced at the trial did not establish as a fact that Mrs Webb died as a result of cancer caused by her industrial injury and that cancer is too common to attribute it to a specific cause on mere speculation. It is the well established rule, said the Supreme Court, that in a compensation proceeding the findings of fact by the trial judge will not be disturbed by the appellate court if sustained by any material evidence. The correctness of the trial court's findings were then discussed by the Supreme Court in the light of the medical testimony adduced at the trial. Apparently the only medical witness called by the appellant was Dr Laws, who had removed Mrs Webb's breast in November 1939. This witness stated that medical science had never found the cause of cancer, that in many instances medical science does not know that cancer will result from certain conditions, that no one knows of any instances in which cancer has resulted from a traumatic condition but that some authorities state that it results from trauma, and that some medical authorities recognize the fact that cancer may or will in some instances result from a traumatic condition. He would not say that cancer is more likely to occur in the part of the body where there has been a trauma but that in his opinion the cancer that developed in Mrs Webb could be attributed to the blow or bruise on her breast. Specifically he testified

If she got a lick there, had discoloration, probably blood under the skin, and that cleared up, I would think that was the result of the lick. I would attribute it to that any way, but nobody can say positively.

On cross examination he stated that the cause of cancer or its cure is not definitely known and that it is conjecture to say that it is. The witness was shown an article by Dr Francis Ward, director of Cancer Research at Columbia University, entitled "Cause of Cancer," wherein it was stated, in part, that

The cause of cancer is not known, though there are two popular superstitions regarding it. One is, that cancer may be produced by a blow, and the other, that cancer is due to a germ. To uphold either of these there is not the slightest evidence.

The witness stated that, although he had not read the article, he "wouldn't swallow it all. That is one man's opinion." He stated that while thousands of times people have a blow, and no cancer develops, there are many instances in which it does. He illustrated his point by stating that women who have had a child are prone to cancer of the uterus, and the cause is traumatic laceration of the cervix.

Three medical witnesses were called by the employer. One, Dr. Horton, testified that in his opinion cancer cannot result from a blow. This witness agreed with the article of Dr. Ward referred to. In this connection he stated that he had read

just last week the report of four men who have had a great deal of cancer research experience, Harvard men. They think now they have found one of the causes of cancer, which is due to the presence in the blood of free hydrocarbon, and they have examined a lot of them. The belief that trauma may cause cancer, of course, I don't know, but such has never been proven.

The claim that a blow causes cancer, this witness stated, "They claim they have discredited that belief." Another medical witness called by the employer, Dr. Cheney, testified that he had treated Mrs. Webb on several occasions in 1936, 1937 and 1938 for a tumor of the abdomen. He stated that no one knows the cause or cure of cancer, the cause of which is speculative. On cross examination, in answer to a question as to whether or not one of the theories in the medical profession as to the cause of cancer is trauma, he replied that some claim that is a theory, "I don't know. It wouldn't be my theory." Dr. Johnson, the other medical witness called by the defendant, agreed with the article by Dr. Ward on the "Cause of Cancer." He stated on cross examination that the theory that a blow, particularly on the breast of a woman, can cause cancer has been advanced on the ground that any irritation might have something to do with cancer, but such a theory has never been proven to be true. In his opinion, the cause of cancer is purely speculative and is not known.

The trial judge, continued the Supreme Court, found that the proof referred to above does not establish as a fact that Mrs. Webb died as the result of a cancer caused by the industrial injury. Three medical witnesses introduced by the employer testified, as noted, that the cause of cancer is purely speculative, that the idea that a blow on the breast could cause cancer had been advanced but never proven to be true. The only medical witness of the petitioner, Dr. Laws, stated that in effect medical science does not know that cancer will result from certain conditions or that it results from traumatic conditions. For this Court, said the Supreme Court, in view of the medical testimony, to hold that the cancer on Mrs. Webb's breast was caused by the blow she received during the course of her employment would rest in pure speculation, conjecture and guess. It was incumbent on the appellant to establish by competent and material proof that death was occasioned by an accident arising out of and in the course of her employment. Such a finding cannot be based on mere speculation or conjecture.

Accordingly, the Supreme Court affirmed the judgment of the trial court in favor of the employer.—*McBrayer v. Dixie Mercerying Co.*, 156 S. W. 408 (Tenn., 1941).

False Imprisonment: Affidavits of Physicians in Insanity Inquest Absolutely Privileged.—Ethel Dyer brought an action for damages for false imprisonment against her former husband and two physicians. She alleged that by virtue of affidavits as to her mental condition made "knowingly, maliciously and falsely" by the three defendants in a proceeding to determine her sanity held before a judge of a county court, who "was misled by these false affidavits," she was adjudged insane and committed to a state hospital for the insane, where she was forced to remain for some twenty-one days. The trial court sustained demurrers interposed by the defendants and the plaintiff appealed to the Supreme Court of Tennessee.

Apparently in the appellate proceedings there was involved only the correctness of the trial court in ruling on the demurrers of the physicians. The physicians contended that even if the statements made in the affidavits were false and were made, as

charged, with malice, they were made in a judicial proceeding under oath, in response to a call for their professional opinion, and were, therefore, absolutely privileged and that no claim for damages can be based thereon. The correctness of the physicians' contentions, in the judgment of the Court, was upheld by the decision of the Supreme Court of Tennessee in *Cookley v. Galyon*, 109 Tenn. 1, 70 S. W. 607, reading, in part, as follows:

There is a class of cases which are absolutely privileged, and depend in no respect for their protection upon their bona fides. The occasion is an absolute privilege, and the only questions are whether the occasion existed, and whether the matter complained of was pertinent to the occasion. In this class are embraced judicial proceedings. The proceedings connected with the judicature of the country are so important to the public good that the law holds that nothing which may be therein said with probable cause, whether with or without malice, can be slander, and, in like manner, that nothing written with probable cause under the sanction of such occasion can be libel.

Applying these principles to this case, the question is not whether the words spoken by the defendant were false and malicious, but were they spoken in a judicial proceeding, and were they relevant and pertinent to the subject of inquiry in that proceeding, or responsive to questions propounded to the defendant by counsel while being examined therein as a witness? If they were, they are absolutely privileged, and the plaintiff's action must fail.

Now, said the Supreme Court of Tennessee, applying the principles set out in the Galyon case, it is apparent that (1) the affidavits complained of were made in a judicial proceeding and (2) the statements therein were pertinent to the subject of inquiry in that proceeding. The affidavits were a vital part of the judicial proceedings before the judge of the county court and the statements therein complained of, whether true or false, were directly in point on the issue for decision of whether or not the person under examination was of unsound mind. Assuming, as we must, the regularity of these judicial proceedings, the judge appointed a guardian ad litem to look after the interest of the person and examined other witnesses, as well as the two physicians on this hearing. Conceding that error was committed in the judgment and that plaintiff was thereby wronged, and that the affidavits were false, as she charged, nevertheless, for the reasons above given, she has no right of action and the action of the trial court in sustaining the demurrers interposed by the physicians was correct.—*Dyer v. Dyer*, 156 S. W. (2d) 445 (Tenn., 1941).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1931 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

11:797-848 (Nov.) 1941

Sputum Studies in Pneumonia. In Vivo and In Vitro Susceptibility of Pneumococci to Sulfapyridine and Sulfathiazole. A. W. Fisch, Detroit—p. 797

*Malignant Neutropenia Following Use of Sulfapyridine. L. M. Goldman, I. Applebaum and W. Antopol, Newark, N. J.—p. 810

Arterial Changes of Skeletal Muscle in Patients with Hypertension of Varied Origin. H. C. Hever and R. W. Keeton, Chicago—p. 818

Egg Albumin Complement Mixtures in Wassermann Test with Normal and Syphilitic Rabbit Serums. J. A. Kolmer, Elmer R. Lynch and Loraine Groskin, Philadelphia—p. 828

Studies of Sicklemur Blood with New Method for Its Rapid Diagnosis. W. J. Tomlinson, Santa Barbara, Calif.—p. 835

Comparative Study of Loughlin Test with Particular Reference to Factors of Experience and Skill in Results Obtained. M. J. Distine, A. W. Ritchie and F. B. Queen, Chicago—p. 842

Malignant Neutropenia After Sulfapyridine.—Goldman and his associates add 2 cases of malignant neutropenia following sulfapyridine therapy to the 28 already reported. From the data on the 30 cases they conclude that the danger of neutropenia is greater when the administration of the drug is prolonged or irregular. The histories of 13 of the 30 patients revealed that the drug had been withdrawn and then reinstated. This suggests sensitization after resumption of treatment. Eleven of the remainder received continuous treatment for ten or more consecutive days and 6 for less than ten days. Of the 12 patients who died, only 1 was given the drug for less than ten days.

Section D

Serum Fraction with Which Antitrichinella (Trichinella Spiralis) Antibody Is Associated. Evelyn Abrams Mauss, Baltimore—p. 73

Sulfathiazole as Antimalarial.—Schwartz and his co-workers used sulfathiazole as an antimalarial for 9 patients who were under treatment for syphilitic meningoencephalitis with artificially induced tertian malaria. Before the antimalarial was used, from three to fifteen chills had been induced. Sulfathiazole,

3 Gm., was administered orally. The initial dose was repeated in four hours, and then 1 Gm. was given every four hours thereafter. The total dose varied from 25 to 50 Gm. Frequent blood counts, urinalyses and blood smears for parasites were made. Blood sulfathiazole levels were obtained throughout the course of chemotherapy. The chills and fever of every patient ceased after treatment with sulfathiazole. The peripheral circulation of 5 patients was apparently cleared of plasmodia. In 1 patient a relapse occurred fifteen days after sulfathiazole was discontinued and in the other 4 there have been no signs of relapse for more than ninety days. The blood of the remaining 4 patients could not be cleared of plasmodia, and the patients experienced relapses twelve, thirteen, sixteen and twenty days, respectively, after chemotherapy was terminated. No serious toxic manifestations followed the administration of sulfathiazole. Further studies of the antimalarial effect of sulfathiazole seem indicated.

Emboli of Brain Tissue in Fetal Lungs. P. Gruenwald, Chicago—p. 879.

Appendical Oxyuriasis.—Ashburn states that in a series of 2,317 surgically removed appendices oxyuriasis were found in 184 (7.94 per cent). The sectioned material of 79 was positive, and the oxyuriasis in 105 were found only by examining the contents expressed from the appendix. The specimens were received from the United States Public Health Service hospitals and from hospitals of the United States Indian Service. The incidence of appendical oxyuriasis among the white beneficiaries of the United States Public Health Service hospitals was 2.88 per cent, among the Indians it was 10.04 per cent and among Eskimos and Aleutians it was 23.97 per cent. The highest incidence occurred in the 7 to 11 year age group, being (for the entire series) 15 per cent for male and 22.22 per cent for female patients. Thereafter the decrease in incidence was gradual until the 32 to 36 year age group, in which a second peak occurred, 7.44 per cent for male and 15.96 per cent for female patients. Appendical infection was rare after the age of 51. Oxyuriasis occurred as frequently in the normal appendix as in the chronically inflamed one and more frequently than in the acutely inflamed appendix.

Fatal Reactions Following Antisyphilitic Treatment.—Hahn states that during twenty-seven years there were 47 fatal reactions to antisyphilitic treatment and that 22 of the deaths were directly attributable to the trivalent arsenicals administered at the syphilis clinic of the Johns Hopkins Hospital. The mortality rate was 1:1,250 patients treated, with 1 death to each 12,000 injections. The mortality rate was three times as great for Negro as for white patients and twice as great for female as for male patients. The more frequent occurrence of acute yellow atrophy among women accounted for the greater mortality among women. Fifteen of 20 patients with this complication were women. Other conditions conducive to hepatic damage were present in at least 8 other patients. Fatal reactions due to dermatitis, blood dyscrasias and arsenical reactions were next in order of frequency. Arsphenamine was responsible for 50 per cent of the fatalities. Fatal reactions, with the exception of the blood dyscrasias, tended to occur after ten or less injections. It is estimated that almost one half of the arsenical reactions might have been prevented by careful consideration of the patient's general physical condition, appropriate modification of therapy, avoidance of technical errors and withdrawal of treatment when signs of intolerance appeared. This precaution could have prevented nearly all deaths due to blood dyscrasias. At the necropsy of 35 patients the most frequent anatomic observations were hepatic necrosis, dermatitis and hypoplasia of the bone marrow.

Sulfanilamide in Gonorrhea and Syphilis.—Brunet and his associates treated 44 patients who had gonorrhea and syphilis with sulfanilamide, arsenicals and bismuth compounds concurrently. A history of previous syphilitic infection was obtained from 18, only 8 of whom had received any previous treatment, which was inadequate. Of the 44 patients, 30 received 2.6 Gm. of sulfanilamide daily without any reaction, 8 were sensitive to this amount but tolerated 1.3 Gm. and 6 took the drug irregularly but still made good progress. Thirty-seven completed their tests of cure of gonorrhea, 5 defaulted before dismissal and 2 lapsed five weeks after admission. The 5 who did not complete all their tests of cure were noninfectious when last seen. Major disturbing reactions from sulfanilamide or from the antisyphilitic drugs were not encountered. One patient had a mild generalized dermatitis, but it disappeared when sulfanilamide was withdrawn, and the antisyphilitic treatment was continued. Four patients had gastrointestinal upsets following the intravenous injection of an arsenical, and anorexia, dizziness, headache and drowsiness disappeared either on the reduction in the dose or the omission of sulfanilamide for several days. The slight cyanosis of the lips disappeared when sulfanilamide was withdrawn.

- Massage in Internal Medicine. C. J. McLoughlin, Rochester, Minn.—p. 674.

Role of Spas in Medical Preparedness.—McClellan states that if the facilities available in the spas of the United States are properly coordinated they can be used to advantage in the preparedness program. The mineral waters of the spas of the United States are of wide variety. The waters of Saratoga Springs, N. Y., contain large quantities of carbon dioxide, which is widely used abroad for the treatment of circulatory and cardiac disorders. A survey shows that there are spa facilities in thirty-three states in one hundred and three localities, with accommodations for 57,491 patients. In eighty-three localities the facilities are for less than 500 patients each, while in eleven states there are one or more spas with accommodations for 1,000 or more patients. These eleven states have approximately 85 per cent of the available facilities. With the exception of the First Army Corps Area, each area has accommodations for more than 2,000 patients. Also, in each area, except the first and the fourth, there are individual localities for 1,000 or more patients. In nearly all localities the physicians of the community can adequately direct the program for patients undergoing treatment. Many of the hotels at spas are not suitable for operation during the entire year, but selected localities could be chosen and the accommodations remodeled for year round operation. Spa facilities should not be neglected in the nation's plan for better health.

Heparin for Preventing Adhesions.—Lehman and Boys believe from results obtained in dogs and in 14 patients that the use of heparin for the prevention of peritoneal adhesions or for the diminution of their reformation after division is theoretically sound. The mechanism is believed to consist in the diminution of the coagulability of the serous exudate which is the response of the peritoneum to injury. However, heparin in preventing the coagulation of exudate prevents the deposition of fibrin in the cut ends of blood vessels, and without adequate hemostasis the use of heparin in the peritoneum will be associated with intra-abdominal hemorrhage. However, if all oozing points are controlled before heparin is introduced, this danger apparently ceases. An enormous number of patients must be treated with heparin before a sufficient number will be reoperated on or examined after death to provide a basis for judging the effectiveness of the intraperitoneal administration of heparin in preventing adhesions in the human being. Until greater experience has been had treatment with heparin should be limited to patients with acute partial or complete intestinal obstruction due to adhesions and particularly to those with previous operations for obstruction or repeated threatening attacks. Heparin should be used only when one is willing to accept the hazard of an insufficiently tried method in preference to a future risk of

significant proportions Heparin should not be used in the abdomen in the presence of an oozing peritoneum after adhesions have been divided or when granulation or subacute inflammatory tissue is present, even if hemostasis is complete

Neutralizing Antibodies in Serums of Mothers and Infants—Rickard and Horsfall determined the antibody content of the serum of 72 young mothers within a few months of delivery and of their 72 infants within twelve days to sixteen months after birth The distribution of antibody levels against

influenza A virus was similar among the mothers and their infants during the first month of life The neutralizing capacity of the serum of only 2 infants was slightly higher than that of their mothers A progressive decrease in the antibody level of the infants occurred during the first four months of life The serum of no infant between 12 and 16 months of age possessed antibodies against influenza A virus The close correspondence between the neutralizing antibody level of the serum of mothers and their infants for the first two months after birth strongly suggested that the concentration of antibodies in the maternal serum determines the concentration in the serum of the child The fact that the concentration of antibodies possessed by infants rapidly decreased during the first four months of life and was not demonstrable at sixteen months may be taken to show that the antibodies were not produced by the child but were foreign substances which were later destroyed or eliminated

Excessive Appetite—McLoan noticed that an excessive appetite was a symptom in unobese children of poor social adjustment almost as frequently as stealing, lying, physical assault and other better known behavior symptoms A large

appetite is normal only after unusual exertion. Persistent longing for food can hardly be considered normal. Mothers frequently report large appetite as a complaint. A child steals food, steals money or works for money with which to buy food, has frequent "snacks" between meals, prowls around at night for food and consumes more food at regular meals than both the parents. The usual reaction of a parent to such a symptom is to reduce the food intake, without realizing that a needed source of emotional gratification is being removed without the supplying of something to take its place. The parent fails to recognize that food is being used as a support and as a means of overcoming or combating a disturbed mood or psychic frustration. A sudden increase in appetite is seen occasionally in children subsequent to the separation of parents, a death in the family, the birth of a sibling, a scholastic or social success of a sibling, the advent of an outsider in the home and major changes in living arrangements which curtail the child's facilities and is seen also when a child in a large family receives less recognition than his siblings. The last-mentioned situation affects children from families in which there is a dearth of social contact and cultural interest. It is also observed when a parent dwells on his or her own unhappy childhood, illnesses and dissatisfactions. The psychoanalytic interpretation of longing for food is that of an intense oral receptive tendency, the wish to be taken care of and to be loved.

*Bronchoscopy Without Aid of Laryngoscope. J. Mikell, Tucson, Ariz.—p. 1063.

Bronchoscopy Without the Laryngoscope.—In approximately five hundred bronchoscopies Mikell passed the bronchoscope without aid of the laryngoscope. The larynx, the pyriform fossae and the adnexa should be examined carefully prior to bronchoscopy. After the examination the laryngoscope should be removed and only the bronchoscope passed. The author believes that the laryngoscope is required only when a tube 5 mm. in diameter or less is used or when a large amount of mucus, which blocks the lumen of the bronchoscope, is being expelled through the larynx. He is convinced that the use of the laryngoscope in bronchoscopy under other conditions is unnecessary and that it makes the procedure more difficult for the patient and for the examiner.

Circulatory Failure in Infections.—Bender states that circulatory failure in acute infectious diseases is due to heart failure and/or peripheral circulatory failure. It is of inestimable importance to determine the exact type of failure, since the treatment of heart failure consists in careful attention to general measures, in the administration of dextrose and possibly in

the use of adrenal cortex extract. In the treatment of peripheral circulatory failure measures to replenish the fluid loss in the system and to correct the abnormal physiologic state are indicated.

Indications for Thyroidectomy.—Cottis states that two thirds of the conditions given a mistaken diagnosis of hyperthyroidism leading to unnecessary operations come under the head of anxiety, neurosis and neurocirculatory asthenia. Organic heart disease and essential hypertension account for the remainder of the mild forms of depression which between the ages of 40 and 60 constitute a danger and must be guarded against. The broad picture is one of nervousness, weakness, tachycardia, emotional disturbances, tremors and loss of weight or constant underweight. When the sensation of choking (globus hystericus) appears it is not surprising that many of the patients come to the surgeon for thyroidectomy. Unfortunately, once enlargement of the thyroid has been mentioned they are eager for operation and are, therefore, an easy prey for the incompetent or dishonest practitioner. Usually a differential diagnosis is not difficult if the following points are considered: In hyperthyroidism some enlargement of the thyroid is present. Thyroid tachycardia is constant; in neurosis it subsides during rest. The skin of patients with hyperthyroidism is warm and moist; the hands and feet of neurotic patients are usually cold and clammy. In hyperthyroidism loss of weight occurs in spite of a good appetite; in neurosis the appetite is usually poor. Patients with hyperthyroidism are usually intolerant of heat; neurotic patients alternate between sensations of heat and of cold. Few patients with hyperthyroidism fail to improve on iodine administration. Those who do fail to improve have a toxic adenoma which is easily palpable. Proper examination should lead to the discovery of organic heart disease and hypertension. In fully developed hyperthyroidism (whether due to toxic adenoma, diffuse hyperplasia or to large nontoxic goiters producing pressure symptoms) the indication for surgical treatment is no longer debatable. The decision whether or not to operate is presented by two types of patients. 1. It appears that many patients with a slight enlargement of the thyroid and mildly toxic symptoms suffer from functional rather than organic hyperthyroidism. There is often a background of domestic or financial troubles. When the psychic factor is corrected, rest and small doses of iodine and sedatives will cure many of them. Recurrences are not infrequent, but they respond to treatment. If the patient is resistant to iodine, operation is indicated before the thyrotoxicosis becomes too great for safe surgical intervention. 2. Older patients with long-standing heart disease (whether caused or complicated by toxic hyperplasia, toxic adenoma or a large nontoxic goiter) are obviously poor surgical risks. Nevertheless, in some of these bad risks, even though the thyroid factor seems debatable, operation has yielded the most brilliant results. Many patients with cardiac disease who are bedridden, who are no longer responding to medical treatment and whose refractory fibrillation is constant may be restored to usefulness by a carefully performed thyroidectomy. Furthermore, patients with paroxysmal tachycardia often respond dramatically to operation. An adenoma of the left pole extending well into the thorax should be kept in mind when such a patient is encountered.

Air Raids and the Child. W. E. R. Mons.—p. 625.

Psychophysiologic Study of Night Blindness.—Wittkower and his collaborators state that of 52 soldiers complaining of night blindness only 1 had a true ocular cause for the complaint. The psychologic data for some of the others were: Another member of the family of 9 suffered from night blindness. Complete blindness in near relatives was reported by 7 and severe anomalies of refraction by 8. Thirty-eight had nervous habits: nail biting, thumb sucking, stuttering, fastidiousness about food and speech disorders. Fear of darkness was excessive in 22. Unusual fear of injury was pronounced in 28. Other fears were fear of dogs, robbers, blindness, bayonet practice, heights, enclosed places, water, fire, contamination and infection. Four men were overtly overaggressive in adolescence or in adult life. Two were criminals. The majority were unaggressive, overcompliant, soft-hearted persons. The aggressiveness of some was more or less completely repressed. Most of the men denied direct prying interests, but questioning disclosed that many of them were unnecessarily inquisitive and curious. Most of the patients were inhibited in their desire to be noticed, while 6 were happy only if they could show off. Nine men stated that they had been night blind since childhood, 16 later in life but before the war, 13 since the blackouts had started and 14 during the war. The onset was gradual in 31 and acute in 21. There was no correlation between the personality types of the men and the mode of onset. Night blindness occurred in 11 patients in the course of a nervous breakdown, and in 6 it was precipitated by terrifying war experiences. In general the night blindness, though phenomenologically the same, was etiologically distinct from that due to nutritional causes and was probably of purely psychologic origin.

Relationship of Rhinology and Laryngology to Thoracic Surgery. C. P. Thomas.—p. 313.

*Relation of Infantile Mastoiditis to Infantile Mortality. P. W. Leathart.—p. 320.

Mastoiditis and Infantile Mortality.—Leathart states that the vast majority of deaths of infants up to 1 year of age are from bronchopneumonia, lobar pneumonia, gastroenteritis and acute bronchitis, that is air-borne or food-borne infections. At postmortem examination of children undiagnosed mastoiditis is frequently discovered, almost exclusively in infants up to and about 1 year of age certified as having died from one or other of the foregoing infections. During a period of two years, postmortem examination of 60 children less than 1 year old who died from an air-borne infection and of 12 who died from a food-borne infection revealed undiagnosed mastoiditis on one or both sides in 59.6 per cent. During these two years approximately 150 infants with a diagnosis of mastoiditis were operated on, with a recovery rate of 80 per cent. All, or nearly all, these infants would have died had not operation been done and death would have been certified as due to an air-borne or a food-borne infection instead of to mastoiditis complicating the air-borne or the food-borne infection. That the diagnosis of this complication is possible, in fact easy, and operative treatment effective is shown by the case sheets of 32 infants with an air-borne or a food-borne infection and mastoiditis. The case sheets revealed that (1) the diagnosis of mastoiditis before operation was correct in every case, (2) in the majority the condition was bilateral, (3) only 2 of the children were more

than 1 year old, (4) the tympanic membrane of a few showed inflammatory changes and in 2 or 3 pus was seen at the fundus, (5) all the patients were seriously ill and the gross dehydration of many was unrelieved by receiving saline solution intravenously, (6) the glands in the posterior triangle of the neck of all the children were enlarged, (7) 6 died after operation and (8) 26 recovered and left the hospital in good condition. Therefore diagnosis and treatment saved 80 per cent of these infants from death. When an air-borne or a food-borne infection in a child less than 1 year old is not improving the probability of mastoiditis should be considered. Examination with the electric auroscope may reveal a pool of pus at the fundus which is too small to appear outside. Sometimes the tympanic membrane is pink or it may be lusterless or wrinkled like crushed tissue paper. Frequently nothing abnormal is seen. There is one constant physical sign: palpable glands in the posterior triangle of the neck, behind the sternomastoid muscle. Other conditions (sepsis of the skin of the head or ear) which produce such enlargement are rarely found in children less than 1 year of age. Mastoiditis in its catarrhal or purulent stage is by far the most common cause of the enlargement in these infants and should be suspected at once. The bottle-fed infant with an air-borne or a food-borne infection and the healthy bottle-fed infant should never be fed while they are lying down. Between feedings they should be propped up and constantly turned from side to side. The adoption of these measures has definitely decreased the incidence of mastoiditis complicating air-borne and food-borne infections among the infants treated at the Royal Liverpool Children's Hospital and has also promoted spontaneous recovery in infants not ill enough to require surgical intervention.

Pulmonary Tuberculosis in the Services.—Aspin and Stalker observed 100 soldiers and airmen suspected of having pulmonary tuberculosis who were sent to a sanatorium from military hospitals and sick posts. According to the final diagnosis, 8 were nontuberculous. Of 10 who previously had been notified that they had tuberculosis only 1 deliberately concealed some essential information because he wanted to join up to get a "soft job." The others felt they were helping their country by enlisting. Eighteen others gave a history of a parent, brother or sister either being treated for pulmonary tuberculosis or dying of the disease. Three fourths of the men were conscripts whose military service amounted to less than a year. While 4 old regulars could muster sixty-four years of service among them, 12 others could not together make up six months of service. The 100 men were divided into two groups—those in whom miniature roentgenograms at enlistment would have revealed lesions suggestive of pulmonary tuberculosis and others in whom it would not have. Study at the sanatorium suggested that abnormal shadowing or displacement of the mediastinum would have been clear enough at enlistment in 46 of the 100 men to have been detected by miniature roentgenography. The stage at which the disease was diagnosed in the men did not differ materially from the stage at which diagnosis is made in civil life.

Bone Changes Due to Fluorine Poisoning.—De Senarclens points out that intoxication with fluorine, like lead poisoning, plays an important part in industrial diseases. The use of cryolite (Na_3AlF_6 , or sodium aluminum fluoride) in the production of aluminum provokes emanation of vapors which contain fluorine and exert a toxic effect on the workers. The author reviews the literature on fluorine poisoning and describes his own experiments on rabbits, rats and goats. He concludes that fluorine has a particular affinity for the skeleton and the teeth. He was unable to produce macroscopic lesions, but the microscopic lesions appeared rapidly, if the intoxication was severe. The lesions are dependent on the storage of the agent in the skeleton, if fluorine is administered in a dose which only slightly exceeds physiologic elimination. Fluorine provokes osteopathy of the osteitis fibrosa type. During the first phase a destruction (osteoclasia) takes place that corresponds to the picture of a progressive atrophy. The second phase is osseous regeneration (osteoplasia, osteosclerosis). Sodium fluoride is more toxic than is calcium fluoride because of its greater solubility. The elimination of fluorine is probably regulated by the parathyroids. The author considers various hypotheses with regard to the pathogenesis of skeletal fluorosis: the calciprivic theory, the theory of a deficiency of mineral salts or of vitamins, as well as the theory which ascribes the osteopathy to a renal lesion. The hypotheses according to which goiter and hyperemia act as pathogenic agents appear erroneous to the author. He suggests a theory which presupposes the presence of a tissue and humoral acidosis resulting in a withdrawal of salts of skeletal origin and in decalcification. Decalcification in an acid milieu takes on the character of osteitis fibrosa. The disturbances of the apposition will be due to an inhibiting action of fluorine on the phosphatase, notably on the second phase of its action (precipitation and distribution of the phosphocalcic salts). The dental lesions consist in damage to the enamel, which becomes lusterless and chalky and exhibits transverse depigmented bands. The friability and wearing away of the teeth, extreme mobility in the alveolus and lesions of the paradentosis type must be attributed to atrophy of the alveolar edges. Other organs exhibit lesions due to fluorine poisoning. Hemosiderosis of the spleen is found in the majority of animals, myocarditis in one fourth and nephrosis in a smaller number of rats and rabbits. Of the 3 goats 1 exhibited glomerular nephritis and another nephrosis. Other disorders were microfollicular goiter, testicular atrophy and chronic gastritis. Intoxication developed in a suckling kid during the administration of fluorine to its mother. Sodium fluoride provoked abortion in 1 of 2 goats.

Effect of Anticoagulant Solutions on Thrombocytes.—Sonder describes his studies on the influence exerted by different anticoagulants on the evolutive forms of thrombocytes. His aim was to find the most suitable solution for the demonstration of thrombocytes in dark field preparations. Among the substances investigated were solutions of magnesium sulfate, sodium citrate, sodium oxalate, a solution designated as liquemin, Corelli's solution, hirudin solution, Lenggenhager's solution and a solution known as liquid. With the aid of these different anticoagulants the thrombocyte could be observed as a cell consisting of cytoplasm and granules. With the aid of magnesium sulfate diverse pictures were observed: star shaped cells, spider or butterfly shape, cells with pseudopodia with club-shaped or flail-like ends, cells with double-contoured pseudopodia, cells with short and long pseudopodia and cells in an irritative or in a quiescent state. The author found a 14 per cent solution of magnesium sulfate particularly suitable. This solution permits the clearest visualization of the active forms and their

evolution. The quiescent forms can be demonstrated by a 2 per cent solution of sodium citrate and still better by a 1 per cent solution of sodium oxalate. Quiescent forms predominate if sodium oxalate solution is used. They are mostly round and exhibit almost no amoeboid movements. The oxalate appears to exert a damaging effect on the thrombocytes. Liquemin solution proved especially effective in demonstrating the various phases of the elimination of fibrin needles after the addition of thrombin solution, the formation of the fibrin reticulum and the dissolving processes of the thrombocytes at the coagulation centers, probably because it has a weaker anticoagulating effect. Liquid is entirely unsuited because of its dissolving effect on the thrombocytes. With regard to the clinical use of anticoagulants the author concludes that sodium citrate solution is best suited for inhibiting coagulation in blood transfusion; the predominance of quiescent forms seems to indicate that there is less danger of thrombosis. However, in a case of hemostatic blood transfusion liquemin is preferable because of its slight inhibiting effect on the coagulation and because it impairs the thrombocyte function less than other anticoagulants, but the rather frequent appearance of piles of thrombocytes indicates a greater danger of thrombosis.

"Gann," Tokyo

35:133-245 (June) 1941. Partial Index

- *Experimental Production of Liver Cirrhosis by Furfural Feeding. W. Nakahara and K. Mori.—p. 208.

Cirrhosis of Liver by Furfural Feeding.—Nakahara and Mori report experiments confirming the successful production of cirrhosis of the liver by furfural feeding in rats. Furfural ($\text{C}_4\text{H}_3\text{O}_2\text{CHO}$), one of the essential constituents of Japanese rice wine (saké), is a practically colorless liquid which has a boiling point of 160 to 162 C. (352 to 355 F.) and which readily polymerizes. When fed with rice in amounts varying from 10 to 50 cc. per kilogram of body weight, furfural may produce early death in animals. Generally speaking, rats fed on these amounts of furfural begin to show evidence of hepatic cirrhosis in sixty to ninety days; much smaller feedings of furfural may not lead to such a pathologic condition until three hundred to five hundred days later. The earliest change in the liver of animals so fed was the development of a granular or nodular surface, especially noticeable in the caudate lobe. While the organ tended toward paleness in color, the nodular parts, varying greatly in size, were never entirely white. When furfural is fed in small amounts over a long period of time, the cirrhotic changes are more or less localized, although the affected areas themselves are even firmer and have more irregular surfaces, as compared with those of animals fed larger amounts of the material. In experiments in which furfural feeding was discontinued after one hundred and forty-two days, the animals dying after discontinuance of the experimental diet showed increasing degrees of fibrosis; the cirrhotic areas in their livers presented firm, distinctly whitish and evenly granular or smooth surfaces. In other organs furfural feeding produced no gross changes. Histologically the early changes are dilatation of the sinusoids with engorgement and some changes in the Glisson capsules, consisting of round cell infiltration, an increase in connective tissue and a distinct proliferation of the transitional epithelial cells. The last mentioned cells appear to be the cellular element which plays a significant part in producing the ductlike structures in furfural cirrhosis. Later they produce the typical picture of annular cirrhosis, and together with the proliferation of connective tissue elements, particularly collagenous and reticular fibers, these cells reduce the size of liver lobules and divide them into coarse netlike structures. In livers with advanced cirrhosis there may occur actual tumor-like enlargement of the parenchyma tissue, composed of lobules containing hypertrophic liver cells. These typical ductlike structures frequently are irregular in size and shape, sometimes showing fantastic convolutions and enlargement of the lumens. Some of these dilated lumens, often cystic and papillar in appearance, may contain amorphous matter suggestive of products of secretion. The authors express the opinion that the cirrhotic changes produced by furfural feeding are initiated by the primary productive interstitial processes, without noticeable necrosis of hepatic cells, and are characterized by the prominent annular picture and proliferation of pseudo bile ducts.

Book Notices

Wounds and Fractures: A Clinical Guide to Civil and Military Practice. By H. Winnett Orr, M.D., F.A.C.S., Chief Surgeon, Nebraska Orthopedic Hospital, Lincoln. Cloth. Price, \$3. Pp. 227, with 137 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1941.

In this purely personal review of a wide experience with traumatic wounds and fractures, Dr. Orr presents his own description of the "Orr method." The work is timely, as the "method" has been widely advocated and used during the present war emergency. In his own words, "The Orr method is not simply a matter of infrequent dressings with a vaseline pack. It calls for all the other essentials of surgical care; namely, adequate primary drainage, protection of the patient's wound against secondary infection, immobilization in correct position and good general care." The general principles which are brought forth have received wide acceptance.

The actual technic used to achieve rigid intrinsic skeletal traction and fixation should not be confused with the principles which may be termed the Orr method. Many of the opinions expressed in this work will not be accepted without argument. Widespread use of fixation and transfixation pins is advocated, but mention of their dangers is not made, particularly when such pins are used in the site of the fracture. The author uses a much more widespread type of plaster fixation than is commonly considered adequate, using double long leg plasters for compound fractures of the tibia and fibula and advocating the use of a double spica dressing even though an adequate reduction and nailing operation has been done in a fracture of the neck of the femur. No ill effects from prolonged immobilization in plaster are recorded; rather the opposite view has been taken, that joint stiffness is the result of inadequate or insufficient immobilization.

In the section devoted to the care of compound, contaminated and infected wounds, there are several opinions expressed which may be questioned. The subject of gas bacillus infection is dismissed in one paragraph with the statement "If gas bacillus infection is present, more extensive provision must be made for drainage and access of air to all parts of the wound, but otherwise the treatment is the same. Correct position of the limb and immobilization of the extremity are just as important as under less dangerous conditions." In the care of a contaminated wound, proper emphasis is laid on adequate exposure of all reaches of the wound, but a minimal amount of attention paid to the actual débridement. Dr. Orr still specifically advocates the use of iodine and alcohol used locally in the preparation of the wound for débridement. No contraindications to the use of rigid pin fixation in a closed plaster are mentioned at any point, yet in inexperienced hands the adoption of this method of therapy might well lead to serious consequences.

It is in the field of compound fractures that the present work will prove of interest, and here the basic principles of the author's method of treatment is the essential contribution of the whole book. He considers every open or compound fracture to be actually or potentially infected. If the wound is a clean one, the purpose is to repair it by aseptic surgical measures and leave it alone; for a soiled or infected wound, to clean it up surgically and provide drainage. This is done by wide open aseptic packing with a petrolatum gauze pack. The petrolatum pack is not a wick to drain the wound or a plug to fill it like a cork. The wound is not distributed or dressed unless pain, swelling, rise in temperature or high white blood cell count gives evidence of a return of inflammation in a wound or the fracture area of sufficient severity to warrant intervention. If this is necessary, the proper surgical drainage should be instituted and the same program again carried out. Rigid fixation of the fracture fragments by one means or another is an essential part of the treatment, not merely the encasement of the limb in a circular plaster of paris splint.

Proper care of traumatic wounds throughout the world has been improved through the efforts of Dr. Orr beyond question. This has been his greatest contribution to the field of surgical practice, and in this work he emphasizes over and over again

the clinical principles on which his views are based. Any disagreement with the technical methods employed by others cannot detract from this fact. It must be remembered that this work presents nothing beyond the author's own experience, and many of the case reports incorporated speak for themselves.

An Account of Twelve Months of Health Defense Containing the Activities of the Health Department of the City of New York for 1940 with Comparative Vital Statistics Tables and a Review of Developments Since 1934. Edited by Savel Zimand. Fiorenzo H. LaGuardia, Mayor. John L. Rice, M.D., Commissioner of Health. Cloth. Price, \$1. Pp. 283, with 25 illustrations. New York, 1941.

For the fourth year in succession, the Annual Report of the Department of Health of the City of New York has appeared in book form and with an editorial approach which represents something more than the traditional recital of work done, budgets allowed, citizens arrested, literature distributed, disadvantages suffered or overcome, achievements hailed and failures explained. Each of these reports has been keyed to a specific phase of health progress in the work of the department. This volume is appropriately titled to catch the current interest in national defense, in which health is an important consideration.

The book presents the various phases of the work of the health department, including the conventional divisions from vital statistics to venereal disease control. The factual tabular material is concentrated at the back of the book, where it does not interfere with easy reading of the narrative summaries of the work of the several departments yet is available when needed. Considerable tabular material which bears direct relationship to accompanying tests is found in the body of the report.

This constitutes a good report of a first class job of public health administration. Physicians reading or scanning the report will be pleasantly impressed with the numerous examples of cooperation between the department of health and the five county medical societies of Greater New York and the New York Academy of Medicine. Aside from its value as a historical record of health administration in the nation's greatest city and the interest attached to the original conception of district administration which is being experimentally worked out in New York City, this book should be useful in public health training schools for all kinds of public health personnel and should also be a reference book of tremendous value in any college or high school library, where it should serve as a rich source of information for studies and project work.

Contribution to the Knowledge of Congenital Dislocation of the Hip Joint: Late Results of Closed Reduction and Arthrographic Studies of Recent Cases. By Erik Severin. Translated from the Swedish by Helen Frey. Acta chirurgica Scandinavica, Vol. LXXXIV, Supplementum 63. Paper. Pp. 142, with 44 illustrations. Stockholm: P. A. Norstedt & Söner, 1941.

The introductory chapter of the history of congenital dislocation is well presented, though only meager recognition is given to Paci, pre-Lorenz attempts of reduction, with a review of statistical data on end results, including these of Lorenz, Lange and the latest reports of Putti (1934), Annovazzi and others. Although the author objects to statistical series which do not contain all cases treated (which seems to be hardly possible to obtain), a certain weeding out for lack of subsequent information is necessary. His statistical study is based on a material of 330 cases which remained after eliminating unsuccessful reductions, cases too old, and the like, and of this group over 90 per cent could be reexamined for the final statistics, leading to three hundred and thirty early results; but his data are valuable because of the homogeneity of his material, which is treated under the same supervision and same method throughout and the percentage of his reexamined cases is high. In his primarily successful cases the late results are based on roentgenologic data, the so-called Wiberg angle being used for the standard of normality and the x-ray end results being divided into six groups, which range from complete anatomic cure to complete redislocation. The reader will be interested in the tabulations of the late end results from the roentgenologic angle, on the observation of 306 cases with 417 hips; also in his tables on relation of age and end result in x-ray terms, especially the relation between development of femoral head and age at reduction, and the relation of deformation of femoral head to age of reduction.

Owing to the extremely critical standard, the author finds that good late results judged from the roentgenologic aspect are found in only one tenth of the cases treated with good primary results.

Chapter 6 is devoted to the development on the healthy side in 190 cases of unilateral congenital dislocation. He finds in no less than 57 of these dysplasias and subluxations, considering all cases in which the angle of inclination of the acetabular roof after the first year of life was 30 degrees or more.

A comparison of late functional results with late roentgenologic findings leads the author to the conclusion that of 448 hips treated with good primary results only about one fourth functioned perfectly five years or more after treatment, which is in contrast to Max Lange, who finds 75 per cent good function in his follow-up series.

The second part of the book is devoted to arthrographic studies made with a contrast medium, parabrodil, for which the author has worked out his special technic. Several pertinent facts are established thereby which otherwise would escape observation, for instance, relationship of the cartilaginous limbus to the head and the ligamentum teres. Especially the degree of penetration of the head into the acetabulum after reduction and progressive changes in such penetration are beautifully illustrated by a number of excellent roentgenograms.

The monograph is well written, carefully prepared both from the historical and the observational angle and excellently illustrated. The x-ray studies of the second part are particularly attractive.

Infant Nutrition: A Textbook of Infant Feeding for Students and Practitioners of Medicine. By Williams McKim Marriott, B.S., M.D. Revised by P. C. Jeans, A.B., M.D., Professor of Pediatrics, College of Medicine, State University of Iowa, Iowa City. Third edition. Cloth. Price, \$5.50. Pp. 475, with 31 illustrations. St. Louis: C. V. Mosby Company, 1941.

This is a treatise on modern infant feeding and nutrition based on sound physiologic and chemical principles. In keeping with modern advances in science, various chapters have been rewritten. The chapter on vitamins is particularly important. The present exploitation of vitamins has left the public, and the practitioner as well, greatly confused. Marriott and Jeans review the subject thoroughly and concisely. Their view that excessive doses of vitamin D retard growth and that concentrated preparations are less efficiently utilized is significant. The chapter on cow's milk now includes a discussion of the low curd tension and soft curd milks which are frequently used in the artificial feeding of infants. The chapter on the diet of the normal infant is a discussion in greater detail with respect to the advantage and disadvantage of feeding various foods based on the nutritional requirements of the infant. The chapter on celiac disease possibly could be more complete in its discussion of the diagnosis with particular reference to cystic disease of the pancreas and the possible factor of food allergy in the celiac syndrome. A new chapter briefly discusses allergy in relationship to infant feeding. The value of sulfanilamide and its derivatives in the treatment of various infections is discussed. The chapter on rickets, tetany and scurvy has been enlarged to include the more recent methods of prophylaxis and treatment with the newer vitamin preparations.

Out of the Test Tube. By Harry N. Holmes, Ph.D. Third edition. Cloth. Price, \$3. Pp. 305, with 102 illustrations. New York: Emerson Books, Inc., 1941.

Scientists with a literary inclination and writers with a scientific bent have discovered that the public is avidly interested in what's going on in science. Unfortunately too many of these writers treat their subject matter in terms of melodramatic heroics, creating nothing more than a distorted caricature of the facts. They paint a picture of scientific research as something carried on at a high emotional pitch like stunt flying or a rescue at sea. The host of real scientists laboring from day to day, year in and year out, to uncover the stuffy but important little facts that serve as the backbone of scientific progress would appear, if the truth was known, as unimaginative dullards in comparison with the fictional heroes created by the popular writers' imaginations.

Fortunately for the public there are a few consummate artists among those who write on scientific subjects. In the forefront of these stands Dr. Harry N. Holmes. Chemistry is fortunate

to have in its ranks a spokesman with his literary talents. In a direct, honest, clear, pictorial style he presents his science in a manner that is not only informative and educational but as entertaining as many books that are read for diversion. With "Out of the Test Tube" and Dr. Holmes's latest textbook on chemistry under his arm a high school or college student is prepared to learn chemistry and like it. While either of these volumes will stimulate his interest in the subject, there is grave peril that together they might be sufficient to make him want to be a chemist.

Medizinische Praxis: Sammlung für ärztliche Fortbildung. Herausgegeben von Prof. Dr. L. R. Grote, Direktor der Medizinischen Klinik des Rudolf-Hess-Krankenhauses Dresden, Prof. Dr. A. Fromme, Direktor der Chirurgischen Abteilung des Stadtkrankenhauses Dresden-Friedrichstadt, Prof. Dr. K. Wernke, Direktor der Staatlichen Frauenklinik zu Dresden, und Prof. Dr. F. Lange, Direktor der Medizinischen Klinik des Stadtkrankenhauses Dresden-Friedrichstadt. Band XXX: Viruskrankheiten des Menschen. Von Professor Dr. med. E. Haagen, Abteilungsleiter am Institut für Infektionskrankheiten "Robert Koch," Berlin. Paper. Price, 10 marks. Pp. 162, with 26 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1941.

The purpose of this volume as expressed by the author in his preface is to furnish a handbook on virus diseases for the practicing physician rather than one for the investigator and specialist. The volume has seriously attempted to meet this need, and the mode of presentation is such as to cover the major points of knowledge from both the technical and the practical side. There is some limitation in bibliography as well as in the points of view. The sections on therapy are essentially primitive and scarcely constitute the type of discussion one would anticipate for the practicing physician. Many of the therapeutic measures would not conform to accepted American standards. Nevertheless the volume has points of value in that it brings together discussions of most of the virus diseases which are of clinical importance. Arrangement by diseases is based more on clinical similarities than on an arbitrary classification of viruses. There is little reason at the present to recommend it for the American physician, since this information can be obtained from textbooks printed in this country, while the present volume will probably not be obtainable.

The Secret of Better Health. By Harold J. Rellly, D.Sc., President of the New York State Society of Physiotherapists. Cloth. Price, \$2.50. Pp. 221, with illustrations. New York: Carlisle House, 1941.

This book apparently promises to give the layman all the advice necessary for good health and long life. It does not live up to its promise. Advice on diet and nutrition is always eagerly sought by the layman. In this book the reader is told that one of the cardinal points to remember in dieting is no "to mix protein and carbohydrates in one meal." Also the soybeans contain no fat. Other bits of misinformation are that "bunions actually are arthritis" and that hypertension is a symptom of old age. The chapter devoted to hypertension leads the reader to believe that the cause is principally overwork and overeating and that the necessary treatment is increasing the elimination through exercise and more roughage in the diet. In spite of the occasional suggestion to "see your doctor first," the reader is likely to try out first the advice given in the book. The book is written in a breezy, smart-cracking style which makes it easy to read; nevertheless it cannot be recommended by the physician for the lay reader.

Housing for Health: Papers Presented Under the Auspices of the Committee on the Hygiene of Housing of the American Public Health Association. Paper. Price, \$1. Pp. 221, with 16 illustrations. New Haven: The Committee, 1941.

This collection of papers presented under the auspices of a committee on housing of the American Public Health Association is of primary interest to the health official or the housing expert. Subjects discussed include health and housing, health centers, health services, housing projects, heating and ventilation of a home, family life as the basis of home planning and the social effects of good housing, as well as others. The practicing physician is also concerned with these problems. In recent years the problem of heating and ventilation of the home has become a popular one. Like the subject of nutrition of the body, every one is talking about it, and the physician is frequently called to act as referee. This book gives him excellent summaries of this topic, as well as the basic principles of healthful housing.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

WEATHER, CLIMATE AND RHEUMATISM

To the Editor:—The Board of Public Welfare is planning to erect within the next few years a new institution for the aged and infirm of the District of Columbia. Plans are already under way for the choice of a location for the new institution. Our present buildings are located on the banks of the Potomac River. The low altitude and the proximity of the river make for considerable dampness in the atmosphere surrounding the home. Fully 50 per cent of our inmates suffer with "rheumatism" in one form or another. Since I began my duties here last June I have heard many patients make the complaint "my rheumatism is much worse since I come down here." Since we have no facilities for adequate physical therapy it has been necessary for me to dispense soliloquies "by the bushel." Would you kindly advise me as to the effect of atmospheric conditions on patients suffering with various types of chronic locomotor diseases? Do you think it advisable to remove the institution to a higher and drier climate if such a measure entails a considerable expense?

Donot P. Cyr, M.D., Blue Plains, D.C.

ANSWER.—Since the days of Charcot and Garrod, dampness and chilling have been condemned by physicians and rheumatic patients as factors which predispose to the onset or aggravation of rheumatic diseases. Despite this general opinion there are few precise data to support it. Glover, who prepared a report on chronic arthritis for the British Ministry of Health (Report No. 52, Ministry of Health, London, 1928) regarded the idea as undoubtedly correct but was unable to find accurate supporting data. Other difficulties present themselves; chief among them is the vagueness of the term "rheumatism" and the fact that atmospheric conditions, weather and climate are made up of variable components—temperature, barometric pressure, atmospheric electricity, humidity and the like.

Probably the chief forms of "rheumatism" encountered in a home for the aged and infirm are osteoarthritis and its secondary fibrositis. Patients with these diseases often complain of the aggravating effects of damp and cold, but they do so less consistently than do patients with rheumatoid arthritis or with primary fibrositis. But such patients do not all act alike; although most patients with rheumatoid arthritis feel better when the temperature and barometer rise and when the humidity falls, some patients actually feel better in winter or with a falling barometer, and with cold, rather than warm, applications (Rentschler, E. B.; VanZant, F. R., and Rowntree, L. G.: Arthritic Pain in Relation to Changes in Weather, *THE JOURNAL*, June 15, 1929, p. 1995). Some patients are apparently disturbed more by changes in barometric pressure than by changes in temperature; others are more susceptible to alterations in humidity. In still other cases, alterations in atmospheric electricity are suspected as the cause of aggravation of symptoms. Rheumatic patients often feel better when they spend the winters in southern Arizona, probably because of the relative constancy in barometric pressure and in humidity and despite the notable fluctuations in temperature (fluctuations of as much as 50 degrees) which occur between the winter days and nights.

Debates on the influence of climate on the incidence of rheumatic diseases seem to be settled more by local patriotism than by scientific data, according to Tegner (*Am. Rheumat. Dis.* 1:249 [Oct.] 1939), who noted that "rheumatism" was as common in the hills of Sweden as on the flat lands of Denmark and Holland; it is supposedly more common in the cold damp seaside parts of England, but in Scandinavian countries rheumatism sanatoriums are generally placed by the sea. Physicians in European countries with much coast line favor the sea air for their rheumatic patients, those in countries with little coast line regard the sea air as dangerous, and those in mountainous countries favor high altitude. Therefore Tegner concluded that in the temperate zone local climate is an unimportant factor in the incidence of chronic rheumatism. In a recent study made in southern Australia no certain relationship was found between the wetness of the season and the incidence of rheumatic fever, and the presence of creeks and rivers played no etiologic role. Nevertheless, in sections where dry heat prevailed there was less rheumatic fever than in those with combined dampness, high rainfall and relatively cold temperature (Report on the Epidemiology of Rheumatic Infection in South Australia, *M. J. Australia* 1:461 [April 6] 1940). In New Haven, Conn., Paul found the highest incidence of rheumatic fever in the two wettest districts investigated (*Tr. A. Am. Physicians* 55:290, 1940).

Faced with such conflicting and unsatisfactory data, those who would plan wisely the erection of an institution for the aged and infirm, who, chiefly because of their age, are subject to certain forms of rheumatism, will have to be guided by factors other than the proximity of a river. Are the inmates with "rheumatism" in the majority? Would it be cheaper to buy a new location away from damp and cold and build thereon a building without special air, temperature and humidity control, or would it be better to rebuild on grounds already owned (and perhaps conveniently situated) modern buildings in which an "artificial climate," suitable for rheumatic patients, can be provided by modern methods of house conditioning?

Since the problem in this particular institution seems to be a rather serious one which involves wise planning for the future, and since the new institution is not to be built for several years, it would appear that an excellent opportunity is afforded for a comprehensive and yet not too laborious study to be made relating the patients' voluntarily expressed symptoms with changes of humidity, temperature and barometric pressure. It is suggested that appropriate and not necessarily costly weather apparatus be set up in the hospital, that daily records of changes be kept (temperature, humidity, barometric pressure, atmospheric electricity) and that they be correlated with such data on aggravated symptoms and signs of rheumatism (including changes in blood sedimentation rates) as patients may exhibit through several changing seasons. This would constitute a valuable contribution to science and represent a far sighted use of public funds.

INJECTION SOLUTIONS FOR HERNIA

To the Editor:—I am using 10 per cent phenol in equal parts of glycerin and water to inject into hernias, using 2 to 5 cc. per injection. My problem is whether this material would be harmful if accidentally injected into the blood stream. Is this solution effective? What solution would you advise as being superior to the one I am using? M.D., New Jersey.

ANSWER.—Solutions of phenol in the concentration described are extremely dangerous for use in the injection treatment of hernia. Many of the accidents of the injection treatment have been due to necrosis caused by varying strengths of phenol solution. Effective sclerosing solutions which do not contain phenol are on the market and consist principally of tannic acid or of sodium salts of certain fatty acids. Many also contain benzyl alcohol as an anesthetic agent. No preparation for use in the injection treatment of hernia has been recognized by the Council on Pharmacy and Chemistry because insufficient follow-up experience in the application of such a preparation has been gained. In a report (*The Present Status of Injection Treatment of Hernia, THE JOURNAL*, Aug. 17, 1940, p. 533) the Council pointed out that the injection method involves less danger of serious complications than does surgery only when employed in selected cases of hernia by those skilled in the injection of suitably standardized solutions of known composition and action. Apparently none of the proprietary preparations on the market are sufficiently well standardized to insure uniformity of composition and activity and should therefore be used only with full cognizance of the dangers involved. Reports in the literature indicate that of the available preparations those consisting of a solution of the sodium salt of certain fatty acids are perhaps less dangerous than those which contain more powerful sclerosing agents.

SULFATHIAZOLE FOR NASAL SPRAY AND SINUSITIS

To the Editor:—I have been using 5 per cent sulfathiazole in distilled water as a nasal spray in chronic sinusitis and upper respiratory infections. Despite using a nonmetallic atomizer (DeVilbiss number 251) and keeping the solution away from the light in a dark glass bottle, I find that this solution becomes dark in a few days and a bit irritating. Can you tell me any method of increasing the stability (it has been suggested to me that by slightly acidifying the solution or keeping it in the icebox this can be done)? When the solution becomes discolored is it less active or more toxic? Are there any contraindications to the use of the fresh solution as a nasopharyngeal spray?

M.D., Pennsylvania.

ANSWER.—It is assumed that the inquirer is referring to a 5 per cent solution of sodium sulfathiazole in distilled water, because sulfathiazole is not soluble to the extent of 5 per cent. If this assumption is correct, then any attempt to acidify slightly the solution of the sodium salt would result in the precipitation of sulfathiazole from the solution when the point of neutrality was reached and, as the solution was made acid, the drug would tend to go into solution again. For that reason it would not be practical to increase the stability of the solution of the sodium salt of sulfathiazole by acidifying it. Discolored solutions of the sulfonamide drugs should never be used, because it means that chemical changes have taken place in the drug which, under certain conditions, render it less active and possibly more toxic.

It has been shown recently that 5 per cent solutions of the sodium salt of sulfathiazole may be definitely irritating to the nasal mucous membrane and, under certain conditions, may cause such damage to the tissues that necrosis and sloughing will result. For this reason it is the general opinion that these solutions should be used with great care.

DOES THE SKIN BREATHE?

To the Editor:—One of a group of teachers has been teaching that "the skin breathes," while the rest do not regard the skin as an organ of breathing and others would like to know if there is any scientific evidence for considering the skin an organ of respiration. They are aware that it is so in the frog during hibernation. They realize that respiration goes on in all living cells, in muscles, kidneys and epithelium, and that each living cell takes oxygen from the blood and lymph and returns carbon dioxide to the lymph and ultimately to the blood. They do not, on that account, speak of kidneys or muscles as breathing organs. They think of the skin as obtaining its oxygen from the blood and lymph and not from the atmosphere. It is realized that the expression "the skin breathes" or "let your skin breathe" has been much used of late in a loose, almost a poetic, way. To a biology teacher this seems like an unfortunate misstatement. I imagine that persons using it often cannot explain what they mean by breathing and are using the word because it sounds good in connection with soaps or clothing. If they are referring to the elimination of carbon dioxide during "insensible perspiration," which is mentioned in some physiology textbooks, elimination would seem to be the better word. To suppose that air enters the sweat glands seems far fetched. I have not been able to find out whether this so-called breathing of the skin is associated with the promulgation of some idea supposed to be hygienic; very likely it is. If hygienic advice is to be given on the basis of supposed fact, the person giving such advice should make sure of the fact underlying it. Such generalizations as "the less clothing you wear the better," which I have heard laymen confidently assert, may do considerable harm, especially among women and children, and are probably the result of teaching by persons who have not been careful enough about so-called facts. I ask your assistance.

L. M. Dithridge, M.D., New York.

ANSWER.—According to tradition the concept of the skin breathing arose many centuries ago when a nobleman in an effort to adorn his young and beautiful wife painted her skin with a coating of gilt paint. Her prompt death with symptoms of suffocation is said to have given rise to this notion. Its modern use is an atavism that should be discarded. What actually happened in the case of the unfortunate lady was interference with loss of heat and water from the skin.

Most gases and urinary constituents are eliminated to some degree by the skin, the total amount varying with different persons and conditions. As a rule, however, most substances are absorbed by the skin as readily as they are eliminated. For instance, if a body area is immersed in a high concentration of carbon dioxide considerable quantities may be absorbed. Perhaps a better way to state the case would be to say that the skin has the capacity to exchange metabolites, but it is incorrect and misleading to say that it breathes.

The comment on the statement that "the less clothing you wear the better" is highly pertinent. Like all generalities, it holds only for certain conditions and circumstances.

WINTER BRONCHITIS

To the Editor:—Please discuss the treatment of the so-called "winter bronchitis," that is chronic hypertrophic vesicular fibroid pulmonary emphysema.

M.D., Alabama.

ANSWER.—Unfortunately there is no specific treatment for this condition. It is a stage in the evolution of a condition that has had its origin in the past and will likely continue to progress. Much may be done in its amelioration. First determine the presence or absence of a causative factor, which may be removed. Cardiovascular disease may be treated; tumors of the lung may sometimes be removed; aneurysms of the aorta do not offer such a good prospect, nor does silicosis. Bronchiectatic cavities are sometimes the source of recurrent infection. Treatment of these is unsatisfactory unless the bronchiectasis is confined to a single lobe, in which case lobectomy may be considered. Infections about the mouth, tonsils and paranasal sinuses must be controlled if possible. Remaining treatment is largely symptomatic.

Protection from extreme changes in temperature is desirable but not always possible. A dry, warm climate is best for patients with abundant sputum and a warm climate by the seashore for those with a dry cough. The use of expectorants sometimes assists in the raising of thick viscid sputum. Steam inhalations, with or without medication, are soothing but have little additional value. If dyspnea and cyanosis exist, oxygen inhalations are helpful. If bronchial spasm occurs epinephrine or theophylline with ethylene diamine will give some relief.

The use of autogenous vaccines has been suggested, but there is little convincing evidence to

DINITROPHENOL CATARACTS

To the Editor:—A patient who took dinitrophenol from September 1934 to April 1935 lost 35 pounds (16 Kg.) in this time. She took three tablets a day. She also took it from April 1935 to November without any loss of weight. In October 1935 cataracts appeared in both eyes. These progressed until in December she had only light projection and light perception and on December 26 was operated on for cataract extraction. On March 3, 1936 the other eye was operated on. She had two accidents and lost the vision in the first eye. In the other eye she had 20/20 vision with correction twenty-six days after the operation. On Feb. 16, 1937 the eye was the same. On July 31, 1939, with the best correction, she could get only 20/40 vision. On Oct. 27, 1939 the right eye was needed at the hospital. On Feb. 6, 1940, with her correction, she got 20/20 vision. On April 14, 1941, with the best correction, she got 20/30. On July 12 the best vision obtainable was 20/30. This vision remained about 20/30 until recently. In September the best vision obtainable was 20/100. The refraction of the eye has changed little since May 1941. I am especially interested in learning whether you have any records of dinitrophenol cataracts follow-up to know if there is any degeneration of the retina and what the expected eventual result may be.

M.D., Pennsylvania.

ANSWER.—In all the cases of dinitrophenol cataract that have been reported to date there has not been any accompanying retinal degeneration, and after eventual removal of the cataract good vision has been maintained. From the description of this case it would appear that some complicating factor must be present to account for the decreased vision. Probably careful perimetric studies of the peripheral as well as the central fields might reveal the cause.

IMMEDIATE TREATMENT OF POISONING

To the Editor:—Several of my patients are enrolled in the American Red Cross first aid course, with a view to becoming instructors in first aid. The textbook used in this course is "American Red Cross First Aid Textbook" (corrected reprint, 1940). On pages 192 and 193 of this manual the first step in the treatment of poisoning is described as the administration of an emetic, such as soapuds, dishwater and salt water. This treatment is prescribed for all forms of poisoning. It is my understanding that in general an emetic should not be given until after the administration of a demulcent when the poison consists of a corrosive substance, such as acids, alkalis and bichloride of mercury. Are these contraindications still considered valid? If so it would seem important that students of first aid under the Red Cross should be informed of these exceptions to the general rule.

M.D., New York.

ANSWER.—As stated in the American Red Cross First Aid Textbook (1940), two main points are to be remembered in the treatment of poisoning: (1) Dilute; (2) wash out. A poison diluted with a large volume of fluid is not absorbed as rapidly as is poison in a more concentrated form. Furthermore, it is easier to induce vomiting if the stomach is full. When a poison is removed it can do no further damage. More specific directions follow with the admonition not to waste time hunting an antidote.

It is to be remembered that these instructions are intended for the trained lay person and not for the physician. They call for treatment which is practically always available and which can be used without danger of causing further damage. If specific antidotes were always at hand they could be used, but it is felt that the directions given are safe and adequate and should be followed, pending the arrival of the physician.

TEMPERATURE OF PATIENT AND CALCULATION OF BASAL METABOLISM

To the Editor:—When determining results of a basal metabolism test it is necessary to correct for subnormal temperatures as well as for those above normal?

Draper Long, M.D., Mosan City, Iowa.

ANSWER.—It is unwise in routine clinical practice to pay much attention to the rate of metabolism when the temperature deviates much from the standard normal. Abnormalities associated with the disease responsible for the change in temperature may affect the rate of metabolism as well as the change in temperature itself.

While some patients exhibit a slightly subnormal level of temperature most of the time, it is not customary in routine clinical practice to make any correction for this variation.

NEURITIS OF TROCHLEAR NERVE AFTER INFLUENZA

To the Editor:—In Queries and Minor Notes in The Journal, Dec. 6, 1941, page 2018, in reply to a query concerning neuritis of the trochlear nerve after influenza, it is stated that "Jello" at least once daily should be offered for its aminoacetic acid content. This is an error which has frequently crops up in the literature and is based on a failure to distinguish between gelatin per se and gelatin desserts. "Jello" is the trade name of one particular brand of gelatin dessert and as such consists of only about 10 per cent gelatin, the remainder being largely sugar. Obviously the consumption of this product will provide but little aminoacetic acid; what is intended is pure gelatin, which contains approximately 10 per cent of this amino acid.

N. R. Gotthoffer, Grayslake, Ill.
